Panama City Laboratory Contribution 06-22
Final draft March 2007, First draft December 2006

Abstract

Life-history traits (size at age, growth rates, size and age at maturity, and fecundity estimates) of bonnethead sharks, *Sphyrna tiburo*, were analyzed for sharks collected along Florida’s Gulf of Mexico coastline between March 1998 and September 2000. A total of 539 sharks were collected. Females obtained a larger predicted asymptotic size (1139 mm and 907 mm TL, respectively) at a slower rate (0.22 mm yr\(^{-1}\) and .36 mm yr\(^{-1}\), respectively) than males for areas combined. Males reached median size at a smaller size (721 mm TL and 821 mm TL, respectively) and at a younger age than females (2.0+ yrs and 3.0+ yrs, respectively). A fecundity estimate of 10 (std. ± 3) pups per year was determined from 50 litters.

Introduction

*Sphyrna tiburo* inhabits shallow, inshore waters of the Western Atlantic and the Eastern Pacific (Compagno 1984). This species feeds mainly on benthic prey items such as crustaceans and mollusks (Cortés et al. 1996, Bethea et al. In Review). Evidence suggests that the bonnethead shark is highly site-attached exhibiting little or no long-distance migratory behavior and thus, little or no mixing of populations (Heupel et al. 2006). Preliminary evidence from mitochondrial DNA suggests no sharp genetic discontinuities (M.S. Shivji, Nova Southeastern University, personal communication). Studies on bonnethead sharks include age and growth, reproduction, metabolism, diet, demography and paternity types (Parsons 1993a, Parsons 1993b, Manire et al. 1995, Cortés and Parsons 1996, Cortés et al. 1996, Carlson and Parsons 1997, Parsons and Carlson 1998, Lombardi-Carlson et al. 2003, Chapman et al. 2004, Bethea et al. In Review). This report summarizes the most recent study of bonnethead sharks life history from three areas along Florida’s Gulf of Mexico coastline (northwestern Florida, Tampa Bay, and Florida Bay; Lombardi-Carlson et al. 2003).

Materials and Methods

**Sampling**

Sharks were collected from three areas along the eastern Gulf of Mexico from March 1998 to September 2000: northwest Florida, Tampa Bay and Florida Bay. Sharks were collected with gill nets. For detailed explanation of sampling protocol, see Lombardi-Carlson et al. 2003.

**Age and growth**

One vertebra was randomly selected from each shark, fixed to a slide and thin sectioned using a Buehler Isomet low-speed saw. The number of narrow translucent bands was recorded to estimate age from each vertebral section. Alternating pairs of bands (one opaque and one translucent) represent 1 year of growth (Parsons 1993b). The birthmark (translucent band) is
deposited in late summer/early fall (July – September) therefore, only six months of growth are
represented between the first and second translucent zones. Thus, a shark with one band (the
birthmark) was assigned an age of 0+ years old, and a shark with 2 bands was 0.5+ years old.

Determination of growth curves
Growth curves were constructed for females and males from each area separately, sexes
combined by area, sexes combined, and sexes and areas combined using the von Bertalanffy
theoretical growth model. Parameters were estimated using least squares non-linear regression
(SAS V.8, SAS Institute, Inc.). The parameters of the von Bertalanffy growth equation ($L_\infty$, $K,$
$t_0$) were compared using maximum likelihood ratio tests as proposed by Haddon (2001). This
method was used to determine differences between sexes within and between areas and areas
combined.

Maturity estimates for size and age
A logistic regression model was fitted to binomial maturity data (immature = 0, mature =
1) for males and females separately by area, sexes combined by area, and sexes and areas
combined to determine maturity estimates (Mollet et al. 2000). The model was fitted using the
method of maximum likelihood (PROC LOGISTIC, SAS V.8, SAS Institute, Inc). The effect of
area was added to the logistic model to test for similarities in size and age at maturity between
areas by sex (SAS V.8, SAS Institute, Inc).

Results and Discussions
Age and growth
A total of 539 sharks were collected during the study (207 in northwest Florida, 176 in
Tampa Bay, and 156 in Florida Bay; Table 1). Due to reader disagreement of vertebral sections,
ten percent (n = 40) were discarded.

Females reached their theoretical maximum size ($L_\infty$) at a slower rate ($K$) than males in
northwest Florida, Tampa Bay, and areas combined, but not in Florida Bay (Table 1). The
predicted asymptotic length ($L_\infty$) was larger for females than males in each area. The largest
predicted asymptotic lengths for males and females were for sharks from northwest Florida
(1007 and 1398 mm TL, respectively; Table 1). Significant differences in the von Bertalanffy
parameters were observed between sexes within and between areas and areas combined (Table
2).

Maturity estimates for size and age
The largest median size and age at maturity for males and females were those from
northwest Florida (830 mm, 3.0+ yrs; 944 mm TL, 4.0+ yrs, respectively; Tables 1, 3, 4, and 5).
Median size and age at maturity for areas combined was 721 mm TL and 2.0+ yrs (males) and
821 mm TL and 3.0+ yrs (females) (Tables 1 and 6). Significant differences in size at maturity
estimates were found for males and females between northwest Florida and Tampa Bay, Tampa
Bay and Florida Bay, and northwest Florida and Florida Bay (Table 7). Significant differences
in age at maturity estimates were also found for males and females between northwest Florida
and Tampa Bay and northwest Florida and Florida Bay, however, no significant differences in
age at maturity were detected for males or females between Tampa Bay and Florida Bay (Table
7).
**Fecundity**

Bonnethead sharks have an annual reproductive cycle with a fairly short gestation period (4-5 months, Parsons 1993a). A total of 50 pregnant females were collected (14 in northwest Florida, 19 in Tampa Bay, and 17 in Florida Bay). There was no significant difference in average litter size among the areas (NWFL 11 ± 3, TB 10 ± 3, FB 10 ± 3). The overall fecundity for all pregnant females was 10 (std. ± 3) pups per year.

**Literature Cited**

Table 1. Life-history parameter estimates ± standard error for male (M), female (F), and sexes combined (C) bonnethead sharks from northwest Florida (NWFL), Tampa Bay (TB), Florida Bay (FB) and areas combined. Size reported as total length in mm. Reported age adjusted from band counts.
