Introduction

During previous SEDAR data workshops considerable time and effort has been devoted to developing methods for back-calculating recreational landings for years before modern data collection programs and landings estimates were implemented. Methods used in past stock assessments included: ratios of commercial landings to recreational landings, estimates from the U.S. Fish and Wildlife Saltwater Angling Survey (SWAS), U.S. Census data as a proxy for recreational fishing effort to produce regression estimates of catch, and most recently the FHWAR (National Survey of Fishing, Hunting, and Wildlife-Associated Recreation Survey) Method.

For the SEDAR 41 Data Workshop (DW) for South Atlantic red snapper, the Recreational Working Group (RWG) will evaluate historic recreational catch information used in SEDAR 24, along with other potential sources to compile historical landings prior to the modern recreational landings time period. This is defined as pre-1981 for the charter and private boat sectors, or pre-Marine Recreational Fisheries Statistics Survey (MRFSS). One method that will be considered is the FHWAR Method (Brennan and Fitzpatrick, 2012) used in SEDAR 28 which will be presented in this document.

National Survey of Fishing, Hunting, and Wildlife-Associated Recreation Survey (FHWAR), U.S Fish and Wildlife Service (USFWS).

The National Survey of Fishing, Hunting, and Wildlife-Associated Recreation Survey has been conducted every 5 years since 1955 and is one of the oldest and most comprehensive recreational surveys. Among other things, its purpose is to gather information on the number of anglers in the United States, including frequency and time spent fishing (FHWAR 1991).

The FHWAR Surveys published in 1991, 1996, 2001, 2006 and 2011 provide summary tables of U.S. population estimates, along with estimates of fishing participation and effort from surveys conducted by the USFWS every five years from 1955 to 1985 (Tables 1 and 2). This information was used to develop an alternative method for estimating coast-wide recreational landings prior to 1981.

FHWAR Method

The two key components from the FHWAR surveys used in this census method are the estimates of U.S. saltwater anglers and the estimates of U.S. saltwater fishing days. The first objective was to determine the total saltwater anglers and saltwater days from the South Atlantic (SA) by using the summary information of U.S. anglers and U.S. saltwater anglers from the FHWAR surveys. The ratio of U.S saltwater anglers to the total U.S anglers was applied to the total number of

anglers for the SA to yield the total saltwater anglers for SA. The same method was used to calculate the total saltwater days for the SA from the FHWAR surveys from 1955-1985. The FHWAR surveys for the South Atlantic included the entire state of Florida, east and west coasts. In order to address the management boundaries for red snapper, the saltwater angler days for Florida's west coast (FLW) were separated from the SA saltwater angler days using the ratio of the MRFSS total angler trips for FLW to the MRFSS total angler trips for NC to FLW. The mean ratio from 1984-1986 was applied to the total saltwater days for the SA from 1955-1985 to remove FLW effort.

Similar to the SWAS, there was a 12-month recall period for respondents participating in the FHWAR surveys from 1955 – 1985. As part of the 1991 FWHAR, a study was conducted to compare the 12- month recall period to a four-month period. This study revealed that the level of recall bias varies for different types of fishing participation and expenditure (FHWAR, 1991).

Consequently, it was necessary to account for possible reporting bias and adjust the angling effort (saltwater days) in the FHWAR Surveys 1955-1985. In the case of red snapper in the South Atlantic, the total saltwater days for the SA 1955-1985 were adjusted for recall bias in the FHWAR surveys using the mean MRFSS total angler trips for the US East Coast (NC-FLE) 1984 to 1986 divided by the total saltwater days from the 1985 FHWAR Survey. This multiplier was then applied to the total SA saltwater days from 1955-1985 to adjust for recall bias. Using the adjusted saltwater days for SA from 1955 – 1985, the next step in this process was estimating landings of red snapper. This was accomplished by calculating the mean CPUE for red snapper in the South Atlantic from the MRFSS landings estimates for 1981 to 1985. This mean CPUE was then applied to the adjusted saltwater days for the SA from 1955-1985 to estimate the historical landings of red snapper for those years (Table 3). Linear interpolation was used to estimate landings for years that the FHWAR surveys were not conducted during 1955-1980. Since historical recreational landings for red snapper were only lacking prior to 1981, the 1985 estimated landings using the FHWAR census method were excluded (Table 4). It should also be noted, since the headboat data in the South Atlantic for red snapper has been extended back in time to 1972, the historic period for the headboat sector is pre-1972. Therefore, the headboat landings will be included with the historical recreational landings from 1972-1980.

Conclusions

The FHWAR method utilizes a combination of information including U.S. angler population estimates and angling effort estimates from 1955 – 1985 FHWAR, along with estimates of recreational effort and landings from the MRFSS 1981 – 1985. The FWHAR method also used both sources of information to adjust for recall bias, an issue that must be addressed when considering using either the SWAS or the FHWAR Surveys for historical recreational landings. By using data from FHWAR and the MRFSS to calibrate this adjustment, the effect of the 12-

month angler recall period is reduced. The historical landings of red snapper that were calculated using this method show a gradual increase from 1955 to 1980, which reflects an evolving recreational fishery and technological advancements (Figure 1).

SEDAR41- DW17 Estimates of Historic Recreational Landings of Red Snapper in the South Atlantic Using the FHWAR Census Method

Addendum

FHWAR Method

The two key components from the FHWAR surveys used in this census method are the estimates of U.S. saltwater anglers and the estimates of U.S. saltwater fishing days. The first objective was to determine the total saltwater anglers and saltwater days from the South Atlantic (SA) by using the summary information of U.S. anglers and U.S. saltwater anglers from the FHWAR surveys. The ratio of U.S. saltwater anglers to the total U.S. anglers was applied to the total number of anglers for the SA to yield the total saltwater anglers for SA. The same method was used to calculate the total saltwater days for the SA from the FHWAR surveys from 1955-1985. The FHWAR surveys for the South Atlantic included the entire state of Florida, east and west coasts. In order to address the management boundaries for red snapper, the saltwater angler days for Florida's west coast (FLW) were separated from the SA saltwater angler days using the ratio of the MRFSS total angler trips for FLW to the MRFSS total angler trips for NC to FLW. The mean ratio from 1984-1986 was applied to the total saltwater days for the SA from 1955-1985 to remove FLW effort.

Similar to the SWAS, there was a 12-month recall period for respondents participating in the FHWAR surveys from 1955 – 1985. As part of the 1991 FWHAR, a study was conducted to compare the 12- month recall period to a four-month period. This study revealed that the level of recall bias varies for different types of fishing participation and expenditure (FHWAR, 1991).

Consequently, it was necessary to account for possible reporting bias and adjust the angling effort (saltwater days) in the FHWAR Surveys 1955-1985. In the case of red snapper in the South Atlantic, the total saltwater days for the SA 1955-1985 were adjusted for recall bias in the FHWAR surveys using the MRFSS and Southeast Region Headboat Survey (SRHS) total angler trips and days, respectively for the US East Coast (NC-FLE) in 1985 divided by the total saltwater days from the 1985 FHWAR Survey. This multiplier was then applied to the total SA saltwater days from 1955-1985 to adjust for recall bias. Using the adjusted saltwater days for SA from 1955 – 1985, the next step in this process was estimating landings of red snapper. This was accomplished by calculating the mean CPUE for red snapper in the South Atlantic from the MRFSS and SRHS landings estimates for 1981 to 1985. This mean CPUE was then applied to the adjusted saltwater days for the SA from 1955-1985 to estimate the historical landings of red snapper for those years (Table 3). Linear interpolation was used to estimate landings for years that the FHWAR surveys were not conducted during 1955-1980. Since historical recreational landings for red snapper were only lacking prior to 1981, the 1985 estimated landings using the FHWAR census method were excluded (Table 4).

Conclusions

The FHWAR method utilizes a combination of information including U.S. angler population estimates and angling effort estimates from 1955 – 1985 FHWAR, along with estimates of recreational effort and landings from the MRFSS and SRHS 1981 – 1985. The FHWAR method also used both sources of information to adjust for recall bias, an issue that must be addressed when considering using either the SWAS or the FHWAR Surveys for historical recreational landings. By using data from FHWAR and the MRFSS to calibrate this adjustment, the effect of the 12-month angler recall period is reduced. The historical landings of red snapper that were calculated using this method show a gradual increase from 1955 to 1980, which reflects an evolving recreational fishery and technological advancements (Figure 1).

Table 3. Estimated red snapper landings using the FHWAR census method, 1955-1985.

Year	Total salt_days SA	Adjusted Effort	Avg CPUE MRFSS & SRHS 81-85	Historic Catch (number)	S.D.	CV
1955	4820112	4153270	0.0151	62825	36774	0.59
