## Summary

This document details shark catches from the South Carolina Department of Natural Resources (SCDNR), Cooperative Atlantic States Shark Pupping and Nursery (COASTSPAN) survey and the SCDNR adult red drum survey, both conducted in South Carolina's estuarine and nearshore waters from 1998-2009. Catch per unit effort (CPUE) in number of sharks per hook hour were used to examine blacknose and/or sandbar shark relative abundance for all SCDNR time series. The SCDNR red drum time series had to be analyzed in two separate time segments (1998-2006 and 2007-2009) due to a change in gear and sampling design. The CPUE for all time series was standardized using a two-step delta-lognormal approach originally proposed by Lo et al (1992) that models the proportion of positive catch with a binomial error distribution separately from the positive catch, which is modeled using a lognormal distribution. Sandbar sharks from the SCDNR COASTSPAN survey showed a fairly stable trend in relative abundance from 1998 to 2003, followed by a slight increasing trend during the mid 2000s. Sandbar sharks from the 1998-2006 SCDNR red drum survey showed a drop in abundance from 1999 to 2000 followed by a more stable trend in the 2000s and blacknose sharks appeared to be stable throughout the time series. Blacknose and sandbar sharks from the 2007-2009 SCDNR red drum survey also showed a relatively stable trend during the three year time frame this survey has been in existence.

## Introduction

In an effort to examine the use of South Carolina's estuarine waters as nursery areas for coastal shark species the South Carolina Department of Natural Resources (SCDNR) Marine Resources Division, in collaboration with the National Marine Fisheries Service's (NMFS) Cooperative Atlantic States Shark Pupping and Nursery (COASTSPAN) Survey began sampling for sharks using longline and gillnet methods in several estuaries within South Carolina. In addition to the estuarine areas sampled specifically for sharks, the SCDNR also samples the shark bycatch from a long-term longline survey designed to monitor adult red drum Sciaenops ocellatus in the coastal waters of South Carolina. This survey was modified from a fixed station to a random stratified station survey in 2007 in response to the needs of stock assessment biologists and to increase coverage along the coast. In addition, the mainline and number of hooks used for the 2007-2009 SCDNR red drum longline survey were reduced to one third of the original mainline length and hook number per set. For these reasons, the SCDNR red drum longline survey was analyzed as two separate time series (1998-2006 and 2007-2009). Relative abundance indices from the SCDNR red drum survey have been previously generated for blacknose sharks covering the time period from 1998 to 2005 (McCandless et al. 2007). In this document, the time series is updated with data through 2006, including recovered depth data.

## Methods

## Sampling design

SC COASTSPAN estuarine sampling locations were selected in the lower reaches of estuaries in depths which would facilitate the deployment and retrieval of gillnets and hand deployed longlines (i.e. current velocity, tidal range, vessel traffic). All estuarine longline sampling occurred inside of inlets and sampling locations varied with regard to distance from nearshore waters. Estuarine sampling was conducted primarily from April through October with the majority of the effort occurring between May and September. Nearshore sampling stations were those previously selected for adult red drum sampling. Nearshore sampling occurred from immediately outside of the surf zone to 8 km offshore with depths ranging from $3-15 \mathrm{~m}$. These sites were primarily live-bottom areas with low relief, consisting of rock or marl outcrops that were encrusted with sessile invertebrates such as sponges, gorgonians and bryozoans. Nearshore sampling occurred throughout the year with the exception of February; however, nearshore sampling was most intense from September through mid-December. The locations of the SC

COASTSPAN and the 1998-2006 SCDNR red drum fixed estuarine and nearshore sampling areas are shown in Figure 1.

In 2007, GADNR red drum sampling protocol was changed to increase geographical and seasonal coverage. Thirty sites are randomly selected from a predetermined list of sites (40-100 sites/strata) during each sampling period (2- month periods: March/April. May/June, July/August, September/October, November/December). Each of four strata (Winyah Bay, Charleston Harbor, St. Helena Sound and Port Royal Sound) is sampled once during each time period (Figure 2). Specific sampling locations within each stratum have been identified and chosen due to bottom type, depth, and in some cases from previous sampling or suggestions from local charter captains.

## Sampling gear and data collection

The SC COASTSPAN longline gear consisted of 305 m of 0.64 cm braided nylon mainline which supported the use of 50 gangions. Each gangion consisted of a $0.5 \mathrm{~m}, 91 \mathrm{~kg}$ test monofilament leader, size120 stainless steel longline snap, $4 / 0$ swivel and a $12 / 0$ circle hook. Prior to the 2000 sampling year the SC COASTSPAN longline was allowed to soak for 45-60 minutes and then retrieved. After retrieval the gear was either reset or moved to a new location, depending on catch. High bait loss was noted on most sets and therefore the sampling strategy was modified in 2000 and the longline was under run at 15-20 minute intervals. SCDNR red drum longline gear consisted of a 272 kg test monofilament mainline that was 1829 m in length for the 1998-2006 time series and 610 m for the 2007-2009 time series and both time series had 30.5 m buoy lines attached at each end. The mainline for both red drum time series was equipped with stop sleeves at 30.5 m intervals to prevent gangions from sliding together when a large fish was captured. The gangions were the same as those used on the SC COASTSPAN longline with the exception that $14 / 0$ and 15/0 circle hooks were employed. For the 1998-2006 SCDNR red drum time series a set consisted of 120 hooks, and for the 2007-2009 time series a set consisted of 40 hooks. Soak times for red drum longline sets were limited to 45 minutes unless conditions or events dictated otherwise.

Station location, water temperature, salinity, and time of day were recorded for each set for all gear types. The sex, weight, fork length, total length, and umbilical scar condition of all sharks were recorded. Umbilical scar condition was recorded in six categories: "umbilical remains," "fresh open," "partially healed," "mostly healed," "well healed," and none. Sharks were then tagged with either a NMFS blue rototag or steel tipped dart tag (M-tag) and released.

## Data Analysis

Catch per unit effort (CPUE) in number of sharks per hook hour were used to examine blacknose and/or sandbar shark relative abundance for all SCDNR time series. The CPUEs were standardized using the Lo et al. (2002) method which models the proportion of positive sets separately from the positive catch. This analysis was done for the following dependent variables: SC COASTSPAN sandbar shark CPUE, 1998-2006 SCDNR red drum survey sandbar shark CPUE and 1998-2006 GADNR red drum survey blacknose shark CPUE, 2007-2009 SCDNR red drum survey sandbar shark CPUE and 2007-2009 SCDNR red drum survey blacknose CPUE. Factors considered as potential influences on all SCDNR longline survey sets were: year (1998-2009; 1998-2006; 2007-2009), month (April - October; April-December; April-December ), depth ( $0-5,>5 \mathrm{~m} ; 0-5,6-10,11-20,21+\mathrm{m} ; 0-9,10+\mathrm{m}$ ), and area (each of the estuaries, off beaches and nearshore stations) for SC COASTSPAN, the 1998-2006 red drum time series and the 2007-2009 red drum time series, respectively. The proportion of sets with positive catch values was modeled assuming a binomial distribution with a logit link function and the positive catch sets were modeled assuming a lognormal distribution.

Models were fit in a stepwise forward manner adding one potential factor at a time after initially running a null model with no factors included (Gonzáles-Ania et al. 2001, Carlson 2002). Each potential factor was ranked from greatest to least reduction in deviance per degree of freedom when compared to the null model. The factor resulting in the greatest reduction in deviance was then incorporated into the model provided the effect was significant at $\alpha=0.05$ based on a Chi-Square test, and the deviance per degree freedom was reduced by at least $1 \%$ from the less complex model. This process was continued until no additional factors met the criteria for incorporation into the final model. The factor "year" was kept in all final models, regardless of its significance, to allow for calculation of indices. Single factors were incorporated first, followed by fixed first-level interactions. All models in the stepwise approach were fitted using the SAS GENMOD procedure (SAS Institute, Inc.). The final models were then run through the SAS GLIMMIX macro to allow fitting of the generalized linear mixed models using the SAS MIXED procedure (Wolfinger, SAS Institute, Inc), in which all interactions including the "year" factor were treated as a random effect. The standardized indices of abundance were based on the year effect least square means determined from the combined binomial and lognormal components.

## Results

## SC COASTSPAN survey - sandbar sharks

A total of 794 sandbar sharks were caught during 502 longline sets from 1998 to 2009. The size range of juvenile sandbar sharks caught by year is displayed in Figure 3. The proportion of sets with positive catch (at least one sandbar shark caught) was $45 \%$. The stepwise construction of each model and the resulting statistics for the mixed models are detailed in Table 1. Model diagnostic plots reveal that the model fit is acceptable (Figures 4a and 4b). The resulting indices of abundance based on the year effect least square means, associated statistics and nominal indices are reported in Table 2 and are plotted by year in Figure 5.

## SCDNR red drum survey (1998-2006) - sandbar sharks

A total of 609 sandbar sharks were caught during 538 longline sets from 1998 to 2006. The size range of juvenile sandbar sharks caught by year is displayed in Figure 6. The proportion of sets with positive catch (at least one sandbar shark caught) was $32 \%$. The stepwise construction of each model and the resulting statistics for the mixed models are detailed in Table 3. Model diagnostic plots reveal that the model fit is acceptable (Figures 7a and 7b). The resulting indices of abundance based on the year effect least square means, associated statistics and nominal indices are reported in Table 4 and are plotted by year in Figure 8.

## SCDNR red drum survey (1998-2006) - blacknose sharks

A total of 655 sandbar sharks were caught during 538 longline sets from 1998 to 2006. The size range of juvenile sandbar sharks caught by year is displayed in Figure 9. The proportion of sets with positive catch (at least one sandbar shark caught) was 33\%. The stepwise construction of each model and the resulting statistics for the mixed models are detailed in Table 5. Model diagnostic plots reveal that the model fit is acceptable (Figures 10a and 10b). The resulting indices of abundance based on the year effect least square means, associated statistics and nominal indices are reported in Table 6 and are plotted by year in Figure 11.

## SCDNR red drum survey (2007-2009) - sandbar sharks

A total of 570 sandbar sharks were caught during 789 longline sets from 2007 to 2009. The size range of juvenile sandbar sharks caught by year is displayed in Figure 12. The proportion of sets with positive catch (at least one sandbar shark caught) was $30 \%$. The stepwise construction of each model and the resulting statistics for the mixed models are detailed in Table
7. Some model diagnostic plots reveal that the model fit may be acceptable, but the histogram for the lognormal model residuals on positive catch rates and the Q-Q plot indicates that the positive catch data are not normally distributed (Figures 13a and 13b). The resulting indices of abundance based on the year effect least square means, associated statistics and nominal indices are reported in Table 8 and are plotted by year in Figure 14.

## SCDNR red drum survey (2007-2009) - blacknose sharks

A total of 381 sandbar sharks were caught during 789 longline sets from 2007 to 2009. The size range of juvenile sandbar sharks caught by year is displayed in Figure 15. The proportion of sets with positive catch (at least one sandbar shark caught) was $22 \%$. The stepwise construction of each model and the resulting statistics for the mixed models are detailed in Table 9. Some model diagnostic plots reveal that the model fit may be acceptable, but the histogram for the lognormal model residuals on positive catch rates and the Q-Q plot indicates that the positive catch data are not normally distributed (Figures 16a and 16b). The resulting indices of abundance based on the year effect least square means, associated statistics and nominal indices are reported in Table 10 and are plotted by year in Figure 17.
