## Introduction

The National Marine Fisheries Service (NMFS) has been monitoring commercial landings and fishing effort of federally managed coastal finfishes in the Gulf of Mexico and U.S. South Atlantic through the Southeast Fisheries Science Center’s Coastal Fisheries Logbook Program (CFLP). The CFLP collects landings and effort data by fishing trip which is submitted by fishers who own or operate a federally permitted commercial fishing vessel. Most data collected by the CFLP are for fisheries managed by the Gulf of Mexico and South Atlantic Fishery Management Councils. The CFLP began in 1990 to obtain a complete census of the coastal fisheries, with the exception of Florida, where only 20 percent of vessels were selected to report. Beginning in 1993, 100 percent of federally permitted Florida vessels were required to report.

Using the CFLP's available catch per unit effort (CPUE) data, an initial index of abundance was created for yellowedge grouper in the Gulf of Mexico (Baertlein and McCarthy, 2010). However, to assess the possibility of serial depletion of yellowedge grouper in adjacent areas, indices with finer special resolution in the Gulf of Mexico were needed. To accomplish this, the Gulf of Mexico was divided into three regions (statistical areas 2-$5,6-11$, and 13-21) and a separate index was constructed for each region. Data were insufficient for index construction on a finer spatial scale.

## Methods

## Available Data

Longline data used from the CFLP database were described in Baertlein and McCarthy (2010). A modified Stephens and MacCall (Stephens and MacCall, 2004) subsetting technique was used in trip selection (Baertlein and McCarthy, 2010) for each of the three regions. It was found, however, that yellowedge positive trips comprised $100 \%$ of the trip selection for some years in region 3 (areas 13-21). This was also the case in the earlier analysis (Baertlein and McCarthy, 2010), but no year had 100\% positive trips selected because trip selection was Gulf-wide and index construction, using the delta-lognormal method of Lo, et. al. (1992), was successful. Since the delta-lognormal model fails if one or more years of data include only positive trips, a lognormal model on positive trips was used for index construction in region 3. Figures 2A and 2B provide species-specific Stephens and MacCall regression coefficients for regions 1 and 2.

## Index Development

Longline catch rate was calculated in gutted pounds per hook. For each trip, catch per unit effort was calculated as:

## CPUE = gutted pounds of yellowedge grouper/ (number of sets *number of hooks per set)

As in previous analyses (Baertlein and McCarthy, 2010), eight factors were considered as possible influences on longline proportion of trips that landed yellowedge grouper and the catch rate of yellowedge grouper. In order to develop a well balanced sample design, the factors were defined as:

## Yellowedge grouper longline

Region 1 - Areas 2-5

| Factor | Levels | Value |
| :---: | :---: | :---: |
| Year | 19 | $1991-2009$ |
| Area(area_cat3)* | 3 | Stat areas 2-3, 4, 5 (see Fig 1.) |
| Days at Sea | 3 | $1-9,10-13,14+$ days |
| Distance between Hooks $_{\text {(hook_cat) }}$ | 2 | $1-25,26+$ feet |
| Number of Crew | 3 |  |
| Season | 4 | Jan-Mar, Apr-Jun, Jul-Sep, Oct-Dec |
| Total hooks fished | 3 | $<18,000 ; 18,000-33,999 ; 34,000+$ hooks |
| (hook_cat2) $^{1}$ | 2 | $<6,6+$ miles |

## Region 2 - Areas 6-11

| Factor | Levels | Value |
| :---: | :---: | :---: |
| Year | 19 | $1991-2009$ |
| Area_(area_cat3)* | 4 | Stat areas 6-7, 8, 9, 10-11 (see Fig 1.) |
| Days at Sea | 3 | $1-5,6-8,9+$ days |
| Distance between Hooks $^{\text {(hook_cat) }}$ * | 2 | $1-25,26+$ feet |
| Number of Crew | 3 |  |
| Season | 4 | Jan-Mar, Apr-Jun, Jul-Sep, Oct-Dec |
| Total hooks fished $^{1}$ | 3 | $<=8,000 ; 8,001-18,999 ; 19,000+$ hooks |
| Longline length | 2 | $=4,>4$ miles |

## Region 3 - Areas 13-21

| Factor | Levels | Value |
| :---: | :---: | :---: |
| Year | 19 | $1991-2009$ |
| Area_(_rea_cat3)* | 3 | Stat areas 13-15, 16-18, 19-21 (see Fig 1.) |
| ${\text { Days at Sea }(\text { away_cat })^{*}}^{\text {Distance between Hooks }}$ | 3 | $1-5,6-9,10+$ days |
| (hook_cat)* | 2 | $1-25,26+$ feet |
| Number of Crew | 2 |  |
| Season | 4 | Jan-Mar, Apr-Jun, Jul-Sep, Oct-Dec |
| Total hooks fished ${ }^{1}$ | 3 | $<=10,000 ; 10,001-28,999 ; 29,000+$ hooks |
| Longline length (length_cat)* | 2 | $<=4,>4$ miles |

*Names in parentheses appear in some figures and tables.
${ }^{1}$ Total hooks fished was only tested in the proportion positive analysis.

Significant affects on the proportion of positive trips and on the CPUE of positive trips of the above factors were tested using general linear model (GLM) analyses. For each GLM analysis of proportion positive trips (regions 1 and 2 only), a type- 3 model was fit, a binomial error distribution was assumed, and the logit link was selected. The response variable was proportion successful trips. During the analysis of catch rates on successful trips (all regions), a type-3 model assuming lognormal error distribution was examined. The linking function selected was "normal", and the response variable was $\log (C P U E)$. The response variable of longline data was calculated as: $\log ($ CPUE $)=\ln$ (pounds of yellowedge grouper/hook). All 2-way interactions among significant main effects were examined. Higher order interaction terms were not examined.

For regions 1 and 2, the final delta-lognormal model was fit using a SAS macro, GLIMMIX (Russ Wolfinger, SAS Institute), as described in Baertlein and McCarthy (2010). In region 3 however, only positive trips were included and a lognormal model was used for index construction. The lognormal model was fit using a PROC MIXED SAS procedure (Version 9.2 SAS Institute).

## Results and Discussion

The final models for the binomial on proportion positive trips (PPT) and the lognormal on CPUE of successful trips were:

## Yellowedge grouper longline 1991-2009:

Region 1 - Areas 2-5:

$$
\begin{gathered}
\text { PPT = Year + Area + Number of Hooks } \\
\text { LOG(CPUE) = Year + Area + Hook Distance + Year*Area }
\end{gathered}
$$

## Region 2 - Areas 6-11:

$$
\begin{gathered}
\text { PPT }=\text { Year + Area } \\
\text { LOG }(\text { CPUE })=\text { Year + Area }+ \text { Hook Distance + Year*Area + Year*Hook Distance }
\end{gathered}
$$

## Region 3 - Areas 13-21: <br> LOG(CPUE) $=$ Year + Days at Sea + Hook Distance + LL length + Area + Year*Area + Year*Days at Sea + Year*LL length

The linear regression statistics and analyses of the mixed model formulations of the final models are summarized in Table 1.

Relative nominal CPUE, number of trips, proportion positive trips, and relative abundance index are provided in Table 2. The delta-lognormal (regions 1 and 2) and lognormal (region 3) abundance indices constructed, with 95\% confidence intervals, are shown in Figure 3.

Plots of the proportion of positive trips per year, nominal cpue, frequency distributions of the proportion of positive trips, frequency distributions of $\log (C P U E)$ for positive catch, cumulative normalized residuals, and plots of chi-square residuals by each main effect for the binomial and lognormal models are shown in Figures 47. Those diagnostic plots indicate that the fit of the data to the lognormal and binomial models was acceptable. There were some outliers among these data, however, and the frequency distribution of $\log (C P U E)$ from these data were somewhat skewed from the expected normal distribution. Those variations from the expected fit of the data were not sufficient to violate assumptions of the analyses, although there were high proportion of positive trips in some years. The observed positive yellowedge grouper trips for region 1 ranged from approximately 75 to $96 \%$, and 80 to $99 \%$ for region 2. Again, region 3 possessed $100 \%$ positive trips for all years.

Yellowedge grouper standardized catch rates for region 1 fell the first two years, remained relatively constant from 1993 through 1999, and generally increased over the remainder of the time series. Coefficients of variation ranged from 0.30-0.53, with higher CVs from 1991-1993, but were generally consistent over the rest of the time series. For region 2, catch rates were lowest in 1993, but had an overall increasing trend through 2008, with peaks in 1997, 2000, 2003, and 2008. However, catch rates in 2009 dropped by $50 \%$ from 2008. Coefficients of variation ranged from 0.24-0.38, with higher CVs from 1991-1993, but were generally consistent over the rest of the time series. Catch rates for region 3 were lowest in 1996 and showed an overall increasing trend after 2000. Coefficients of variation remained relative constant throughout the time series, ranging from 0.31-0.37. Results from the previous Gulf-wide analysis (Baertlein and McCarthy, 2010) were most similar to the results of regions 1 and 2. The catch rates remained relatively constant from 1993 through 2002, but rose steadily from 2003 through 2008, and dropped-off in 2009. However, the coefficients of variation from the Gulf-wide model were noticeably lower ranging from 0.15 to 0.23 .

## Acknowledgements

Thanks to Drs. John Walter and John Quinlan for the valuable discussions, advice, and help regarding methods for identifying yellowedge grouper trips and defining separate regions for analyses.

Figure 2. Regression coefficients from the Stephens \& MacCall analyses. Positive coefficients signify species that had positive associations with the target species. The magnitude of the coefficients indicates the predictive impact of each species. The value for "non-cooccurring" is the regression intercept and denotes the probability a trip was fishing in the target species' habitat, but did not report any of the listed species. Species included were reported on at least one percent of longline trips in (A) region 1 of the Gulf of Mexico and (B) region 2 of the Gulf of Mexico. Stephens \& MacCall selected trips for region 3 of the Gulf of Mexico were not used.
A.

## Yellowedge grouper Gulf of Mexico Longline - Areas 2-5 Stephens \& MacCall 1\% occurrence

B.

## Yellowedge grouper Gulf of Mexico Longline - Areas 6-11 Stephens \& MacCall 1\% occurrence

Figure 3. Yellowedge grouper nominal CPUE (solid circles), standardized CPUE (open diamonds) and upper and lower 95\% confidence limits of the standardized CPUE estimates (dashed lines) for vessels fishing longline gear in (A) region 1 of the Gulf of Mexico, (B) region 2 of the Gulf of Mexico, and (C) region 3 of the Gulf of Mexico.
A. Region 1 - Areas 2-5
