¹This document describes a BAM application to red grouper; for use in SEDAR 24, the model would be customized to red snapper.

1 Note

Previously a working paper from SEDAR 19, this document describes an application of the Beaufort Assessment Model (BAM) to red grouper. For application to red snapper, details of the assessment model would be customized to the stock in question. However, the basic structure of the BAM, described below, is expected to remain the same.

2 Overview

The primary model in this assessment was a statistical catch-at-age model (Quinn and Deriso 1999), implemented with the AD Model Builder software (Otter Research 2004). In essence, a statistical catch-at-age model simulates a population forward in time while including fishing processes. Quantities to be estimated are systematically varied until characteristics of the simulated populations match available data on the real population. Statistical catch-at-age models share many attributes with ADAPT-style tuned and untuned VPAs.

The method of forward projection has a long history in fishery models. It was introduced by Pella and Tomlinson (1969) for fitting production models and then used by Fournier and Archibald (1982), Deriso et al. (1985) in their CAGEAN model, and Methot (1989) in his stock-synthesis model. The catch-at-age model of this assessment is similar in structure to the CAGEAN and stock-synthesis models. Previous versions of this assessment model have been used in past SEDAR assessments of reef fishes in the U.S. South Atlantic, such as red porgy, black sea bass, tilefish, snowy grouper, gag grouper, greater amberjack, red snapper, vermilion snapper, and Spanish mackerel. The present version of this code, customized for SEDAR 19 red grouper, includes a number of improvements, including addition of a capability for modeling time-varying and/or density-dependent catchability, as suggested by a recent 2009 SEDAR procedural workshop on catchability.

3 Model configurations and equations

Model equations are detailed in Table 1, and AD Model Builder code for implementation is supplied in Appendix 1. An input data file for red grouper is included as Appendix 2. A general description of the assessment model follows:

Natural mortality rate The natural mortality rate (M) was assumed constant over time, but decreasing with age. The form of M as a function of age was based on Lorenzen (1996). The Lorenzen (1996) approach inversely relates the natural mortality at age to mean weight at age W_a by the power function $M_a = \alpha W_a^\beta$, where α is a scale parameter and β is a shape parameter. Lorenzen (1996) provided point estimates of α and β for oceanic fishes, which were used for this assessment. As in previous SEDAR assessments, the Lorenzen estimates of M_a were rescaled to provide the same fraction of fish surviving through the oldest observed age (26 years) as would occur with constant $M = 0.14$ from the DW. This approach using cumulative mortality is consistent with the findings of Hoenig (1983) and Hewitt and Hoenig (2005).

Stock dynamics In the assessment model, new biomass was acquired through growth and recruitment, while abundance of existing cohorts experienced exponential decay from fishing and natural mortality. The population was assumed closed to immigration and emigration. The model included age classes 1 – 16+, where the oldest age class 16+ allowed for the accumulation of fish (i.e., plus group). Initial numbers at age were estimated in the model, but were penalized if they deviated from the stable age structure that resulted by assuming a constant, historical fishing mortality equal to the geometric mean fishing mortality for the first three years following model implementation (i.e., the geometric mean fishing mortality from 1976-1978).

Growth Mean size at age of the population (total length, TL) was modeled with the von Bertalanffy equation, and weight at age (whole weight, WW) was modeled as a function of total length. Parameters of growth and conversions (TL-WW) were estimated by the DW and were treated as input to the assessment model. For fitting length composition data, the distribution of size at age was assumed normal with CV estimated by the assessment

model. For fishery length composition data collected under a size limit regulation, the normal distribution of size at age was truncated at the size limit, such that length compositions of landings would include only fish of legal size, and length compositions of discards would include only fish below the size limit. Mean length at age of landings and discards were computed from these truncated distributions, and thus average weight at age of landings and discards may differ from that in the population at large.

Sex transition Red grouper are a protogynous hermaphrodite. Transition from female to male was modeled with a logistic function, estimated by the DW.

Maturity Female maturity was modeled with a logistic function; parameters for this model were provided by the DW and treated as input to the assessment model. Males were assumed to be fully mature starting at age two (all age-1 fish were considered female).

Spawning biomass Spawning biomass was modeled as the weight of mature individuals in the population (males+females) at the time of spawning, where sex ratio at age was provided by the DW. For red grouper, peak spawning was considered to occur in mid-April.

Recruitment Recruitment was predicted from spawning biomass using a Beverton–Holt spawner-recruit model. Steepness, h , is a key parameter of this model; however, because it is often difficult to estimate steepness (h) reliably (Conn et al. 2010), a prior distribution was used to restrict estimates of h to plausible values (SEDAR 2009b). Estimated recruitment was conditioned on the Beverton–Holt model, potentially with autocorrelated residuals.

Landings Time series of landing from four fisheries were modeled: commercial line (handline, longline), commercial other (pots, traps, trawl, diving, miscellaneous), headboat, and general recreational (MRFSS). Landings were modeled with the Baranov catch equation (Baranov 1918) and were fitted in either weight or numbers, depending on how the data were collected (1000 lb whole weight for commercial fisheries, and 1000 fish for headboats/recreational).

Discards As with landings, discard mortalities (in units of 1000 fish) were modeled with the Baranov catch equation (Baranov 1918), which required estimates of discard selectivities (described below) and release mortality rates. Discards were assumed to have a mortality probability of 0.2 for all fisheries, as suggested by the DW.

Fishing For each time series of landings and discard mortalities, a separate full fishing mortality rate (F) was estimated. Age-specific rates were then computed as the product of full F and selectivity at age.

Selectivities In most cases, selectivities were estimated using a parametric approach. For most fisheries and indices, selectivities were estimated as a two-parameter logistic model. Exceptions were the commercial-other fishery and the MARMAP index, which were assumed to have dome-shaped (double logistic) selectivity, and required estimating four parameters. The commercial-other fishing mode partially mirrored the MARMAP selectivity (three of the four parameters were assumed equal). The inflection of the ascending limb was set equal to the age associated with a given regulatory period's size limit in this case. This parametric approach reduces the number of estimated parameters and imposes theoretical structure on the estimates. Critical to estimating selectivity parameters are age and size composition data. Prior distributions were used on selectivity slope parameters to stabilize estimation and keep them within reasonable values.

Selectivity of each fishery was fixed within each period of size-limit regulations, but was permitted to vary among periods. Fisheries experienced three periods of size-limit regulations (no limit prior to 1984, 12-inch limit during 1984–1991, and 20-inch limit from 1992–2008). Ideally, a model would have sufficient age composition data from each fishery over time to estimate selectivities in each period of regulations. That was not the case here, and thus additional assumptions were applied to define selectivities, as follows. Because the MRFSS collected little age or length composition data on red grouper until recently, headboat and general recreational fisheries were assumed to have the same selectivities in the first two regulatory periods. Commercial lines selectivity was also set equal for the first and second regulatory period.

Selectivities of discards were partially estimated, assuming that discards consisted primarily of undersized fish, as implied by observed length compositions of discards. The general approach taken for discard selectivities was that the value for age-1 fish was estimated, age-2 fish were assumed to have full selection, and selectivity for older age

fish was set at the age-specific probability of being below a fixed size (e.g., the size limit) given the estimated normal distribution of size at age. Given available data on discards, some additional assumptions were necessary; in particular, all fisheries were assumed to have the same discard selectivity function.

Indices of abundance The model was fit to two fishery independent indices of abundance (a Florida Keys RVC survey 1994–2008; and a MARMAP chevron trap survey 1991–2008) and to three fishery dependent indices of abundance (headboat 1978–2008; MRFSS 1991–2008; and commercial lines 1993–2008). Predicted indices were conditional on selectivity of the survey/gear and were computed from numbers at age at the midpoint of the year or, in the case of commercial lines, weight at age.

Catchability Several options for catchability were implemented for the red grouper assessment following recommendations of a 2009 SEDAR procedural workshop on catchability. In particular, capabilities for including density dependence, linear trends, and random walks were implemented. Parameters for these models could be estimated or fixed based on a priori considerations.

Biological reference points Biological reference points (benchmarks) were calculated based on maximum sustainable yield (MSY) estimates from the Beverton–Holt spawner-recruit model with bias correction. Computed benchmarks included MSY, fishing mortality rate at MSY (F_{MSY}), and spawning biomass (total mature biomass) at MSY (SSB_{MSY}). These benchmarks are conditional on the estimated selectivity functions. The selectivity pattern used here was the effort-weighted selectivities at age, with effort from each fishery (including discard mortalities) estimated as the full F averaged over the last three years of the assessment.

Fitting criterion The fitting criterion was a penalized likelihood approach in which observed landings and discards were fit closely, and observed composition data and abundance indices were fit to the degree that they were compatible. Landings, discards, and index data were fit using lognormal likelihoods. Length and age composition data were fit using multinomial likelihoods.

In addition to likelihoods, several penalties and prior distributions were included in the compound objective function. In some cases, as with stock-recruit autocorrelation, steepness, and selectivity slope parameters, priors were applied. Penalties on initial age-structure, catchability variation, and recruitment deviations were also implemented. Priors and penalties were applied to maintain parameter estimates near reasonable values, and to prevent the optimization routine from drifting into parameter space with negligible gradient in the likelihood.

We included a capability for each component of the likelihood to be weighted by user-supplied values (for instance, to give more influence to desired data sources). However, for initial runs of the red grouper assessment model, all weights were set to 1.0 with exception of ω_7 and ω_8 , which were set to 0.0 (effectively removing penalties on initial and final recruitment deviations).

Model testing Experiments with a reduced model structure indicated that parameters estimated from the “Beaufort” model were unbiased and could be recovered from simulated data with little noise (cf., SEDAR 2007). Further, the general model structure has passed several rounds of independent peer review. As an additional measure of quality control, red grouper code and input data were examined by multiple analysts to ensure accuracy. This combination of testing and verification procedures suggest that the assessment model is implemented correctly and can provide an accurate assessment of red grouper stock dynamics.

Table 3.1. General definitions, input data, population model, and negative log-likelihood components of the statistical catch-at-age model applied to red grouper. Hat notation ($\hat{}$) indicates parameters estimated by the assessment model, and breve notation ($\breve{}$) indicates estimated quantities whose fit to data forms the objective function.

Quantity	Symbol	Description or definition
General Definitions		
Index of years	y	$y \in \{1976 \dots 2008\}$
Index of ages	a	$a \in \{1 \dots A\}$, where $A = 16^+$
Index of size-limit periods	r	$r \in \{1 \dots 3\}$ where 1 = 1976 – 1983 (no size limit), 2 = 1984 – 1991 (12-inch TL limit), and 3 = 1992 – 2008 (20-inch limit)
Index of length bins	l	$l \in \{1 \dots 45\}$
Length bins	l'	$l' \in \{160, 190, \dots, 1510\text{mm}\}$, with midpoint of 30mm bin used to match length compositions. Largest 11 length bins treated as a plus group, but retained for weight calculations.
Index of fisheries	f	$f \in \{1 \dots 4\}$ where 1=commercial lines, 2=commercial other, 3=recreational headboat, 4=general recreational (MRFSS)
Index of discards	d	$d \in \{1 \dots 3\}$ where 1=commercial lines, 2=recreational headboat, 3=general recreational (MRFSS)
Index of CPUE	u	$u \in \{1 \dots 5\}$ where 1 = commercial lines, 2 = headboat, 3 = MRFSS, 4 = FL Keys Visual Survey, 5 = MARMAP chevron trap
Input Data		
Proportion female at age	ρ_a	Monotonically decreasing; determined by DW; assumed constant across years
Proportion females mature at age	m_a	Logistic increase with age; determined by DW; assumed constant across years
Spawning date	t_{spawn}	Fraction denoting the proportional time of year when spawning occurs. Set to 0.315 for red grouper by assuming peak spawning occurs in mid-April.
Observed length compositions	$p_{(f,d,u),l,y}^\lambda$	Proportional contribution of length bin l in year y to fishery f, d (landings or discards) or index u
Observed age compositions	$p_{(f,u),a,y}^\alpha$	Proportional contribution of age class a in year y to fishery f or index u .
Length comp. sample sizes	$n_{(f,d,u),y}^\lambda$	Effective number of length samples collected in year y from fishery f , discards d , or index u (often set to number of collection events due to non-independence of samples)
Age comp. sample sizes	$n_{(f,u),y}^\alpha$	Effective number of age samples collected in year y from fishery f or index u
Observed fishery landings	$L_{f,y}$	Reported landings in year y from fishery f . Commercial L in whole weight, and rec L in numbers of fish.
CVs of landings	$c_{f,y}^L$	Assumed 0.05

Table 3.1. (continued)

Quantity	Symbol	Description or definition
Observed abundance indices	$U_{u,y}$	$u = 1$, commercial lines (weight), $y \in \{1993 \dots 2008\}$ $u = 2$, headboat (numbers), $y \in \{1978 \dots 2008\}$ $u = 3$, MRFSS (numbers), $y \in \{1991 \dots 2008\}$ $u = 4$, FL Keys visual survey (numbers), $y \in \{1994 \dots 2008\}$ $u = 5$, MARMAP chevron trap (numbers), $y \in \{1990 \dots 2008\}$
CVs of abundance indices	$c_{u,y}^U$	$u = \{1 \dots 5\}$ as above. Annual values estimated from delta-lognormal GLM for $u = 1, 2, 3, 5$, and from knowledge of sampling design for $u = 4$. Each time series was scaled to a mean of 1.0
Natural mortality rate	M_a	Function of weight at age (w_a): $M_a = \alpha w_a^\beta$, with estimates of α and β from Lorenzen (1996). Lorenzen M_a then rescaled based on Hoenig estimate.
Observed total discards	$D'_{d,y}$	Discards (1000 fish) in year y from fishery d .
Discard mortality rate	δ_d	Proportion discards by fishery d that die. The DW recommended $\delta_d = 0.2$ for all fisheries.
Observed discard mortalities	$D_{d,y}$	$D_{d,y} = \delta_d D'_{d,y}$
CVs of dead discards	$c_{d,y}^D$	Assumed 0.05

Population Model

Mean length at age	l_a	Total length (midyear); $l_a = L_\infty(1 - \exp[-K(a - t_0 + 0.5)])$ where K , L_∞ , and t_0 are parameters estimated by the DW
CV of l_a	\hat{c}_a^λ	Estimated variation of growth, assumed constant across ages.
Age-length conversion of population	$\psi_{a,l}^u$	$\psi_{a,l}^u = \frac{1}{\sqrt{2\pi}(\hat{c}_a^\lambda l_a)} \frac{\exp[-(l'_i - l_a)^2]}{(2(\hat{c}_a^\lambda l_a)^2)}$, the Gaussian density function. Matrix ψ^u is rescaled to sum to one within ages, with the largest size a plus group. This matrix is constant across years and is used only to match length comps of fishery independent indices.
Age-length conversion of landings	$\psi_{f,a,l,y}^L$	$\psi_{f,a,l,y}^L = \begin{cases} \frac{1}{\sqrt{2\pi}(\hat{c}_a^\lambda l_a)} \frac{\exp[-(l'_i - l_a)^2]}{(2(\hat{c}_a^\lambda l_a)^2)} & : l_a \geq l_{\text{limit}} \\ 0 & : \text{otherwise} \end{cases}$ where l_{limit} is the size limit for fishery f in year y (and would be treated as 0 prior to regulations). Annual matrices $\psi_{f,\cdot,y}^L$ are rescaled to sum to one within ages, with the largest 11 length bins fit as a plus group.
Age-length conversion of discards	$\psi_{d,a,l,y}^D$	$\psi_{d,a,l,y}^D = \begin{cases} \frac{1}{\sqrt{2\pi}(\hat{c}_a^\lambda l_a)} \frac{\exp[-(l'_i - l_a)^2]}{(2(\hat{c}_a^\lambda l_a)^2)} & : l_a < l_{\text{limit}} \\ 0 & : \text{otherwise} \end{cases}$ where l_{limit} is the size limit for fishery d in year y (and could be treated as ∞ prior to regulations). Annual matrices $\psi_{d,\cdot,y}^D$ are rescaled to sum to one within ages, with the largest size a plus group.
Mean length at age of landings and discards	$\xi_{(f,d),a,y}^{L,D}$	Mean length at age from $\psi_{f,\cdot,y}^L$ for landings or $\psi_{d,\cdot,y}^D$ for discards
Individual weight at age of population	w_a	Computed from length at age by $w_a = \theta_1 l_a^{\theta_2}$ where θ_1 and θ_2 are parameters from the DW

Table 3.1. (continued)

Quantity	Symbol	Description or definition
Individual weight at age of landings and discards	$w_{(f,d),a,y}^{L,D}$	Computed from length at age by $w_{(f,d),a,y}^{L,D} = \theta_1(\xi_{(f,d),a,y}^{L,D})^{\theta_2}$
Fishery and index selectivities	$s_{f,u}, s_{f,a,r}$	$s_{f,a,r} = \begin{cases} \frac{1}{1+\exp[-\hat{\eta}_{1,f,r}(a-\hat{\alpha}_{1,f,r})]} & :f = 1, 3, 4; u = 4 \\ \left(\frac{1}{\max s_{(f,u),a,r}} \right) \left(\frac{1}{1+\exp[-\hat{\eta}_{1,(f,u),r}(a-\hat{\alpha}_{1,(f,u),r})]} \right) \\ \left(1 - \frac{1}{1+\exp[-\hat{\eta}_{2,(f,u),r}(a-\hat{\alpha}_{1,(f,u),r} + \hat{\alpha}_{2,(f,u),r})]} \right) & :f = 2; u = 5 \end{cases}$ <p>where $\hat{\eta}_{1,(f,u),r}$, $\hat{\eta}_{2,(f,u),r}$, $\hat{\alpha}_{1,(f,u),r}$, and $\hat{\alpha}_{2,(f,u),r}$ are estimated parameters. Not all parameters were estimated for each fishery (or index) and each period of regulations; some parameters were fixed as described in the text. For instance, commercial hand line selectivity for the first regulatory period was set to commercial hand line selectivity in the second period. Likewise, general recreational selectivity in the first two regulatory periods was set to estimates obtained for the headboat fishery. For the RVC index, a declining logistic model was specified, with 100% selection at the first age class (the slope of the logistic decline in selectivity was estimated).</p>
Discard selectivity	$s'_{d,a,r}$	$s'_{d,1,r}$ estimated; $s'_{d,2,r}$ set to 1.0; $s'_{d,3+,r}$ set equal to the age-specific probability of total length below the size limit in period r . All fisheries with observed discards were assumed to have the same discard selectivity.
Fishing mortality rate of landings	$F_{f,a,y}$	$F_{f,a,y} = s_{f,a,y} \hat{F}_{f,y}$ where $\hat{F}_{f,y}$ is an estimated fully selected fishing mortality rate by fishery and $s_{f,a,y} = s_{f,a,r}$ for y in the years represented by r
Fishing mortality rate of discards	$F_{d,a,y}^D$	$F_{d,a,y}^D = s'_{d,a,r} \hat{F}_{d,y}^D$ where $\hat{F}_{d,y}^D$ is an estimated fully selected fishing mortality rate of discards by fishery
Total fishing mortality rate	$F_{a,y}$	$F_{a,y} = \sum_f F_{f,a,y} + \sum_d F_{d,a,y}^D$
Total mortality rate	$Z_{a,y}$	$Z_{a,y} = M_a + F_{a,y}$
Apical F	F_y	$F_y = \max(F_{a,y})$
Abundance at age	$N_{a,y}$	$N_{1,1976} = \frac{0.8\hat{R}_0\hat{h}S_{equil}}{0.2\phi_0\hat{R}_0(1-\hat{h})+(\hat{h}-0.2)S_y} \exp(\hat{R}_{1976})$ $\hat{N}_{2+,1976} \text{ estimated subject to penalties for deviating from equilibrium conditions expected given assumptions about initial fishing mortality (see "Objective Function")}$ $N_{1,y+1} = \frac{0.8\hat{R}_0\hat{h}S_y}{0.2\phi_0\hat{R}_0(1-\hat{h})+(\hat{h}-0.2)S_y} \exp(\hat{R}_{y+1}) \text{ for } y \geq 1976$ $N_{a+1,y+1} = N_{a,y} \exp(-Z_{a,y}) \quad \forall a \in (1 \dots A-1)$ $N_{A,y} = N_{A-1,y-1} \frac{\exp(-Z_{A-1,y-1})}{1-\exp(-Z_{A,y-1})}$ <p>Parameters \hat{R}_0 (asymptotic maximum recruitment) and \hat{h} (steepness) are estimated parameters of the spawner-recruit curve, and \hat{R}_y are estimated annual recruitment deviations in log space. The bias correction is $\varsigma = \exp(\sigma^2/2)$, where σ^2 is the variance of recruitment deviations. Quantities ϕ_0, S_y, and S_{equil} are described below.</p>

Table 3.1. (continued)

Quantity	Symbol	Description or definition
Abundance at age (mid-year)	$N'_{a,y}$	Used to match indices of abundance $N'_{a,y} = N_{a,y} \exp(-Z_{a,y}/2)$
Abundance at age at time of spawning	$N''_{a,y}$	Assumed mid-April to correspond with peak spawning $N''_{a,y} = \exp(-t_{\text{spawn}} Z_{a,y}) N_{a,y}$
Unfished abundance at age per recruit at time of spawning	NPR_a	$NPR_1 = 1 \times \exp(-t_{\text{spawn}} M_1)$ $NPR_{a+1} = NPR_a \exp[-(M_a(1 - t_{\text{spawn}}) + M_{a+1}t_{\text{spawn}})] \quad \forall a \in (1 \dots A - 1)$ $NPR_A = \frac{NPR_{A-1} \exp[-(M_{A-1}(1 - t_{\text{spawn}}) + M_A t_{\text{spawn}})]}{1 - \exp(-M_A)}$
Unfished spawning biomass per recruit	ϕ_0	$\phi_0 = NPR_1 w_1 \rho_1 m_1 + \sum_{a=2}^A NPR_a w_a (\rho_a m_a + (1 - \rho_a))$
Spawning biomass	S_y	$S_y = N''_{1,y} w_1 \rho_1 m_1 + \sum_{a=2}^A N''_{a,y} w_a (\rho_a m_a + (1 - \rho_a))$ Also referred to as spawning stock biomass in units of total mature biomass (males + females). All males greater than one year of age were assumed mature.
Initialization mortality at age	Z_a^{init}	$Z_a^{init} = M_a + \exp(\log(F_{a,1976}) + \log(F_{a,1977}) + \log(F_{a,1978}))/3$
Initial equilibrium abundance at age	N_a^{equil}	Obtained using methods of Caswell (2001) assuming Z_a^{init} as a constant force of mortality
Initial equilibrium spawning biomass	S_{equil}	$S_{equil} = N_a^{equil} w_1 \rho_1 m_1 + \sum_{a=2}^A N_a^{equil} w_a (\rho_a m_a + (1 - \rho_a))$
Population biomass	B_y	$B_y = \sum_a N_{a,y} w_a$
Landing at age in numbers	$L'_{f,a,y}$	$L'_{f,a,y} = \frac{F_{f,a,y}}{Z_{a,y}} N_{a,y} [1 - \exp(-Z_{a,y})]$
Landing at age in weight	$L''_{f,a,y}$	$L''_{f,a,y} = w_{f,a,y}^L L'_{f,a,y}$
Discard mortalities at age in numbers	$D'_{d,a,y}$	$D'_{d,a,y} = \frac{F_{d,a,y}^D}{Z_{a,y}} N_{a,y} [1 - \exp(-Z_{a,y})]$
Discard mortalities at age in weight	$D''_{d,a,y}$	$D''_{d,a,y} = w_{d,a,y}^D D'_{d,a,y}$

Table 3.1. (continued)

Quantity	Symbol	Description or definition
Index catchability	$q_{u,y}$	$q_{u,1976} = \hat{q}_u^0 f(\text{density})$ $q_{u,y+1} = q_{u,y} f_y(\text{trend}) f_y(\text{random}) f_y(\text{density}) \text{ for } y \geq 1976$ Here, $f_y(\text{density}) = (B'_0)^{\hat{\psi}} (B'_y)^{-\hat{\psi}}$, where $\hat{\psi}$ is a parameter to be estimated, $B'_y = \sum_{a=a'}^A B_{a,y}$ is annual biomass above some threshold age a' , and B'_0 is virgin biomass for ages a' and greater. In practice, a' should be set high enough to give a reasonable summary of exploitable biomass. The function $f(\text{trend})$ provides a model for linear trend in catchability up until 2003, where technology effects were thought to saturate (see SEDAR 19 DW report): $f_y(\text{trend}) = \begin{cases} 1.0 & : y = 1976 \\ f_{y-1}(\text{trend}) * (y - 1976) \beta_q & : 1976 < y \leq 2003 \\ f_{2003}(\text{trend}) & : 2003 < y \end{cases}$ <p>Finally, $f_y(\text{random}) = \exp(\epsilon_{u,y})$ are lognormal catchability deviations which allow for a random walk in catchability when penalties are placed on the $\epsilon_{u,y}$ (see “Ob- jective Function”). In practice, only 1-2 of the three catchability function may be used at any one time to achieve parameter identifiability. Catchability from fishery-independent surveys was assumed constant.</p>
Predicted landings	$\check{L}_{f,y}$	$\check{L}_{f,y} = \begin{cases} \sum_a L''_{f,a,y} & : f = 1, 2 \\ \sum_a L'_{f,a,y} & : f = 3, 4 \end{cases}$
Predicted discard mortalities	$\check{D}_{d,y}$	$\check{D}_{d,y} = \sum_a D'_{d,a,y}$
Predicted length compositions of fishery independent data	$\check{p}_{u,l,y}^\lambda$	$\check{p}_{u,l,y}^\lambda = \frac{\sum_a \psi_{a,l} s_{u,a,y} N'_{a,y}}{\sum_a s_{u,a,y} N'_{a,y}}$
Predicted length compositions of landings	$\check{p}_{f,l,y}^\lambda$	$\check{p}_{f,l,y}^\lambda = \frac{\sum_a \psi_{f,a,l,y}^L L'_{f,a,y}}{\sum_a L'_{f,a,y}}$
Predicted length compositions of discards	$\check{p}_{d,l,y}^\lambda$	$\check{p}_{d,l,y}^\lambda = \frac{\sum_a \psi_{d,a,l,y}^D D'_{d,a,y}}{\sum_a D'_{d,a,y}}$
Predicted age compositions	$\check{p}_{(f,u),a,y}^\alpha$	$\check{p}_{(f,u),a,y}^\alpha = \frac{L'_{(f,u),a,y}}{\sum_a L'_{(f,u),a,y}}$
Predicted CPUE	$\check{U}_{u,y}$	$\check{U}_{u,y} = \begin{cases} \hat{q}_{u,y} \sum_a w_{f=u,a,y}^L N'_{a,y} s_{u,a,r} & : u = 1 \\ \hat{q}_{u,y} \sum_a N'_{a,y} s_{u,a,r} & : u = 2, 3, 4, 5 \end{cases}$ <p>where $s_{u,a,r}$ is the selectivity of the relevant fishery in the year corresponding to y. Selectivity for the general recreational index included landed and discarded fish.</p>

Objective Function

Multinomial length compositions	Λ_1	$\Lambda_1 = -\omega_1 \sum_{f,d,u} \sum_y \left[n_{(f,d,u),y}^\lambda \sum_l (p_{(f,d,u),l,y}^\lambda + x) \log \left(\frac{(p_{(f,d,u),l,y}^\lambda + x)}{(p_{(f,d,u),l,y}^\lambda + x)} \right) \right]$ <p>where ω_1 is a preset weight and $x = 1e-5$ is an arbitrary value to avoid log zero. The denominator of the log is a scaling term. Bins are 30 mm wide.</p>
---------------------------------	-------------	--

Table 3.1. (continued)

Quantity	Symbol	Description or definition
Multinomial age compositions	Λ_2	$\Lambda_2 = -\omega_2 \sum_{f,u} \sum_y \left[n_{(f,u),y}^\alpha \sum_a (p_{(f,u),a,y}^\alpha + x) \log \left(\frac{(\check{p}_{(f,u),a,y}^\alpha + x)}{(p_{(f,u),a,y}^\alpha + x)} \right) \right]$ where ω_2 is a preset weight and $x = 1e-5$ is an arbitrary value to avoid log zero. The denominator of the log is a scaling term.
Lognormal landings	Λ_3	$\Lambda_3 = \omega_3 \sum_f \sum_y \frac{\left[\log \left((L_{f,y} + x) / (\check{L}_{f,y} + x) \right) \right]^2}{2(\sigma_{f,y}^L)^2}$ where ω_3 is a preset weight and $x = 1e-5$ is an arbitrary value to avoid log zero or division by zero. Here, $\sigma_{f,y}^L = \sqrt{\log(1 + (c_{f,y}^L)^2)}$.
Lognormal discard mortalities	Λ_4	$\Lambda_4 = \omega_4 \sum_d \sum_y \frac{\left[\log \left((\delta_d D_{d,y} + x) / (\check{D}_{d,y} + x) \right) \right]^2}{2(\sigma_{d,y}^D)^2}$ where ω_4 is a preset weight and $x = 1e-5$ is an arbitrary value to avoid log zero or division by zero. Here, $\sigma_{d,y}^D = \sqrt{\log(1 + (c_{d,y}^D)^2)}$.
Lognormal CPUE	Λ_5	$\Lambda_5 = \sum_u \omega_5 \sum_y \frac{\left[\log \left((U_{u,y} + x) / (\check{U}_{u,y} + x) \right) \right]^2}{2(\sigma_{u,y}^U)^2}$ where ω_5 is a preset weight and $x = 1e-5$ is an arbitrary value to avoid log zero or division by zero. Here, $\sigma_{u,y}^U = \sqrt{\log(1 + (c_{u,y}^U)^2)}$.
Constraint on recruitment deviations	Λ_6	$\Lambda_6 = \omega_6 \left[R_{1976}^2 + \sum_{y > 1976} (R_y - \hat{\varrho} R_{y-1})^2 \right]$ where R_y are recruitment deviations in log space, $\omega_6 = 1$ is a preset weight and $\hat{\varrho}$ is the estimated first-order autocorrelation
Additional constraint on initial recruitment deviation	Λ_7	$\Lambda_7 = \omega_7 (R_{1976}^2)$ where ω_7 is a preset weight
Additional constraint on final recruitment deviations	Λ_8	$\Lambda_8 = \omega_8 \left(\sum_{y \geq 2007} R_y - \hat{\varrho} R_{y-1} \right)^2$ where ω_8 is a preset weight
Penalty on random walk on catchability	Λ_9	$\Lambda_9 = \omega_9 \sum_u \sum_y \frac{\epsilon_{u,y}^2}{2(\sigma_u^q)^2}$ where ω_9 is a preset weight and σ_u^q is a control variable input by the user defining the standard deviation of the random walk process. As σ_u^q increases, one essentially estimates each deviation as a free parameter, while values close to zero allow little variation in annual catchability.
Penalty on initial age structure	Λ_{10}	$\Lambda_{10} = \sum_{a=2}^A (\omega_{10} (\hat{N}_{a,1976} - N_a^{equil})^2)$ where ω_{10} is a preset weight.
Prior distributions and penalties	Λ_{11}	Several diffuse prior distributions were imposed on parameters to keep them in reasonable parameter spaces. This included \hat{h} , $\hat{\rho}_R$, \hat{c}_a^λ , $\hat{\psi}$, and $\hat{\eta}_{1,(f,u),r}$: $\Lambda_{11} = \frac{(\hat{h} - E(h))^2}{\sigma_h^2} + \frac{(\hat{c}_a^\lambda - E(c_a^\lambda))^2}{\sigma_c^2} + (\rho_R - E(\rho_R))^2 + \sum_{f,u} (\hat{\eta}_{1,(f,u),r} - E(\eta_{1,(f,u),r}))^2,$ where expected values $E(\theta)$ are supplied by the analyst.
Total objective function	Λ	$\Lambda = \sum_{i=1}^{11} \Lambda_i$ Objective function minimized by the assessment model

#####Likelihood Component Weighting#####
##Weights in objective fcn
1.0 #landings
1.0 #discards
1.0 #length comps
1.0 #age comps
1.0 #RVC index
1.0 #CVT index
1.0 #commercial HAL index
1.0 #HB index
1.0 #MRFSS index
1.0 #S-R residuals
0.0 #constraint on early recruitment deviations
0.0 #constraint on ending recruitment deviations
100.0 #penalty if F exceeds 3.0 (reduced by factor of 10 each phase, not applied in final phase of optimization)
100.0 #weight on tuning F (penalty not applied in final phase of optimization)
#0.0 #penalty on deviation in CV at age
#0.0 #penalty on first difference in CV at age

#bias adjustment (multiplier) for rec landings (MRFSS)
1.0

##log catchabilities (initial guesses)
-13.0 #RVC survey
-13.0 #Marmap CVT
-8.0 #commHAL (index in weight)
-13.0 #HB
-13.0 #MRFSS
#rate increase switch: Integer value (choose estimation phase, negative value turns it off)
-1
##annual positive rate of increase on all fishery dependent q's due to technology creep
0.0
# DD q switch: Integer value (choose estimation phase, negative value turns it off)
-1
##density dependent catchability exponent, value of zero is density independent, est range is (0.1,0.9)
0.0
##SE of density dependent catchability exponent (0.128 provides 95% CI in range 0.5)
0.128
#Age to begin counting D-D q (should be age near full exploitation)
4

```

```

##Random walk switch:Integer value (choose estimation phase, negative value turns it off)
-3

#Variance (sd^2) of fishery dependent random walk catchabilities (0.03 is near the sd=0.17 of Wilberg and Bence
0.03
0.03
0.03

##log mean F's (initial guesses)
-3.0          #commHAL
-4.0          #commOther
-5.0          #HB
-3.0          #MRFSS

#Initialization F as a proportion of first few assessment years (set to 1.0 without evidence otherwise)
1.0

#log mean F's for discards (initial guesses)
-5.0          #commHAL discards
-5.0          #HB discards
-3.0          #MRFSS discards

#Early commercial discard F as a proportion of later period
1.0

#Early HB discard F as a proportion of later period
1.0

#multiplicative adjustment to landings/discards CVs
5.0

#Tuning F (not applied in last phase of optimization)
0.35

#Year for tuning F
2008

##threshold sample sizes for length comps (set to 99999.0 if sel is fixed)
1.0 #RVC
1.0 #CVT
1.0 #HAL
1.0 #Cother
1.0 #HB
1.0 #HB discards
1.0 #REC

#threshold sample sizes (greater than or equal to) for age comps
1.0 #CVT
1.0 #HAL
1.0 #HB
1.0 #REC
#
#Ageing error matrix (columns are true age 1-20, rows are ages as read for age comps)
