1. SEDAR PROCESS DESCRIPTION

SouthEast Data, Assessment, and Review (**SEDAR**) is a cooperative Fishery Management Council process initiated in 2002 to improve the quality and reliability of fishery stock assessments in the South Atlantic, Gulf of Mexico, and US Caribbean. SEDAR seeks improvements in the scientific quality of stock assessments and the relevance of information available to address fishery management issues. SEDAR emphasizes constituent and stakeholder participation in assessment development, transparency in the assessment process, and a rigorous and independent scientific review of completed stock assessments.

SEDAR is managed by the Caribbean, Gulf of Mexico, and South Atlantic Regional Fishery Management Councils in coordination with NOAA Fisheries and the Atlantic and Gulf States Marine Fisheries Commissions. Oversight is provided by a Steering Committee composed of NOAA Fisheries representatives: Southeast Fisheries Science Center Director and the Southeast Regional Administrator; Regional Council representatives: Executive Directors and Chairs of the South Atlantic, Gulf of Mexico, and Caribbean Fishery Management Councils; and Interstate Commission representatives: Executive Directors of the Atlantic States and Gulf States Marine Fisheries Commissions.

SEDAR is organized around two workshops and a series of webinars. First is the Data Workshop, during which fisheries, monitoring, and life history data are reviewed and compiled. The second stage is the Assessment Process, which is conducted via a series of webinars, during which assessment models are developed and population parameters are estimated using the information provided from the Data Workshop. Third and final is the Review Workshop, during which independent experts review the input data, assessment methods, and assessment products. The completed assessment, including the reports of all 3 workshops and all supporting documentation, is then forwarded to the Council SSC for certification as ‘appropriate for management’ and development of specific management recommendations.

SEDAR workshops are public meetings organized by SEDAR staff and the lead Cooperator. Workshop participants are drawn from state and federal agencies, non-government organizations, Council members, Council advisors, and the fishing industry with a goal of including a broad range of disciplines and perspectives. All participants are expected to contribute to the process by preparing working papers, contributing, providing assessment analyses, and completing the workshop report.

SEDAR Review Workshop Panels consist of a chair, 3 reviewers appointed by the Center for Independent Experts (CIE), and three reviewers appointed from the SSC of the Council having jurisdiction over the stocks being assessed. The Review Workshop Chair is appointed by the Council from their SSC. Participating councils may appoint additional representatives of their SSC, Advisory, and other panels as observers.

2. MANAGEMENT OVERVIEW

2.1. Reef Fish Fishery Management Plan and Amendments

Original FMP:

The Reef Fish Fishery Management Plan was implemented in November 1984. The regulations, designed to rebuild declining reef fish stocks, included: (1) prohibitions on the use of fish traps, roller trawls, and powerhead-equipped spear guns within an inshore stressed area; and, (2) data reporting requirements.

Description of Action	FMP/Amendment	Effective Date
Allowed 2-day charter-for-hire possession limit on trips that extend beyond 24 hours, provided the vessel has two licensed operators aboard, and each passenger can provide a receipt to verify the length of the trip. Limited other fishermen fishing under a bag limit to a single day possession limit. Established a longline and buoy gear boundary at approximately the 50 fathom depth contour west of Cape San Blas, Florida and the 20 fathom depth contour east of Cape San Blas, inshore of which the directed harvest of reef fish with longlines and buoy gear was prohibited and the retention of reef fish captured incidentally in other longline operations (e.g., sharks) was limited to the recreational bag limit. Limited trawl vessels to the recreational size and bag limits of reef fish. Established fish trap permits, allowing up to a maximum of 100 fish traps per permit holder. Prohibited the use of entangling nets for directed harvest of reef fish. Retention of reef fish caught in entangling nets for other fisheries was limited to the recreational bag limit. Established the fishing year to be January 1 through December 31.	Amendment 1	1990
Commercial reef fish permit moratorium established for three years	Amendment 4	1992

Fish trap endorsement and three year moratorium established	Amendment 5	1994
Extended commercial reef fish permit moratorium until January 1996.	Amendment 9	1994
Commercial reef fish permit moratorium extended until December 30, 2000. Reef fish permit requirement established for headboats and charter vessels.	Amendment 11	1996
10-year phase-out of fish traps in EEZ established (February 7, 1997 – February 7, 2007).	Amendment 14	1997
Established a 12” total length minimum size limit.	Amendment 16B	1999
Commercial reef fish permit moratorium extended until December 31, 2005.	Amendment 17	2000
(1) Prohibits vessels from retaining reef fish caught under recreational bag/possession limits when commercial quantities of Gulf reef fish are aboard, (2) adjusts the maximum crew size on charter vessels that also have a commercial reef fish permit and a USCG certificate of inspection (COI) to allow the minimum crew size specified by the COI when the vessel is fishing commercially for more than 12 hours, (3) prohibits the use of reef fish for bait except for sand perch or dwarf sand perch, and (4) requires electronic VMS aboard vessels with federal reef fish permits, including vessels with both commercial and charter vessel permits (implemented May 6, 2007).	Amendment 18A	2006
Also known as Generic Essential Fish Habitat (EFH) Amendment 2. Established two marine reserves off the Dry Tortugas where fishing for any species and anchoring by fishing vessels is prohibited.	Amendment 19	2002

3-year moratorium on reef fish charter/headboat permits established	Amendment 20	2002, but implementation deferred until June 16, 2003
Continued the Steamboat Lumps and Madison-Swanson reserves for an additional six years, until June 2010. In combination with the initial four-year period (June 2000-June 2004), this allowed a total of ten years in which to evaluate the effects of these reserves.	Amendment 21	2003
Permanent moratorium established for commercial reef fish permits.	Amendment 24	2005
Permanent moratorium established for charter and headboat reef fish permits, with periodic reviews at least every 10 years.	Amendment 25	2006
Addressed the use of non-stainless steel circle hooks when using natural baits to fish for Gulf reef fish effective June 1, 2008, and required the use of venting tools and dehooking devices when participating in the commercial or recreational reef fish fisheries effective June 1, 2008.	Amendment 27	2008
Reduced the harvest of gray triggerfish in order to end overfishing and rebuild the stock. Adjusted the allocation of gray triggerfish catches between recreational and commercial fisheries to 79% and 21%, respectively, and set management thresholds and targets to comply with the Sustainable Fisheries Act (SFA) ($F_{30\%SPR}$). Increased the minimum size limit for gray triggerfish to 14" fork length.	Amendment 30A	2008
Established additional restrictions on bottom longline gear in the eastern Gulf of Mexico to reduce bycatch of endangered sea turtles. (1) Prohibits the use of bottom longline gear shoreward of the 35-fathom contour from June through August; (2) reduces the number of longline vessels operating in the fishery through	Amendment 31	2010

an endorsement provided only to vessel permits with a demonstrated history of landings, on average, of at least 40,000 pounds of reef fish annually with fish traps or longline gear during 1999-2007; and (3) restricts the total number of hooks that may be possessed onboard each reef fish bottom longline vessel to 1,000, only 750 of which may be rigged for fishing. The boundary line was initially moved from 20 to 50 fathoms by emergency rule effective May 18, 2009. That rule was replaced on October 16, 2009 by a rule under the Endangered Species Act moving the boundary to 35 fathoms and implementing the maximum hook provisions.		
Modified the gray triggerfish rebuilding plan based on a 2011 gray triggerfish update assessment, which determined that the stock was not rebuilding on target. Reduced the commercial and recreational annual catch limits to 64,100 and 241,200 pounds whole weight respectively, and reduced the commercial and recreational annual catch targets to 60,900 and 217,100 pounds whole weight respectively. A fixed closed season from June 1 through July 31 was established for the commercial and recreational sectors. Established a commercial trip limit of 12 gray triggerfish, and a recreational bag limit of 2 gray triggerfish per angler bag limit within the 20 reef fish aggregate bag limit.	Amendment 37	2013

2.2. Generic Amendments

Generic Sustainable Fisheries Act Amendment: partially approved and implemented in **November 1999**, set the Maximum Fishing Mortality Threshold (MFMT) for most reef fish stocks at $F_{30\%}$ SPR. Estimates of maximum sustainable yield, Minimum Stock Size Threshold (MSST), and optimum yield were disapproved because they were based on SPR proxies rather than biomass based estimates.

Generic ACL/AM Amendment: Established in-season and post-season accountability measures for all stocks that did not already have such measures defined. This includes the “other shallow-water grouper

species” complex. The accountability measure states that if an ACL is exceeded, in subsequent years an in-season accountability measure will be implemented that would close fishing when the ACL is reached or projected to be reached.

2.3. Emergency and Interim Rules

Emergency Rule - Implemented May 18, 2009 through October 28, 2009: Prohibited the use of bottom longline gear to harvest reef fish east of 85°30' W longitude in the portion of the exclusive economic zone (EEZ) shoreward of the coordinates established to approximate a line following the 50–fathom (91.4–m) contour as long as the 2009 deepwater grouper and tilefish quotas are unfilled. After the quotas have been filled, the use of bottom longline gear to harvest reef fish in water of all depths east of 85°30' W longitude are prohibited [74 FR 20229].

Emergency Rule - Implemented May 3, 2010 through November 15, 2010: NMFS issued an emergency rule to temporarily close a portion of the Gulf of Mexico EEZ to all fishing [75 FR 24822] in response to an uncontrolled oil spill resulting from the explosion on April 20, 2010 and subsequent sinking of the Deepwater Horizon oil rig approximately 36 nautical miles (41 statute miles) off the Louisiana coast. The initial closed area extended from approximately the mouth of the Mississippi River to south of Pensacola, Florida and covered an area of 6,817 square statute miles. The coordinates of the closed area were subsequently modified periodically in response to changes in the size and location of the area affected by the spill. At its largest size on June 1, 2010, the closed area covered 88,522 square statute miles, or approximately 37 percent of the Gulf of Mexico EEZ.

2.4. Management Parameters and Projection Specifications

Table 2.4.1. General Management Information

Species/Management Unit	Gray Triggerfish
Management Unit Definition	Gulf of Mexico
Management Entity	Gulf of Mexico Fishery Management Council
Management Contacts SERO / Council	Steven Atran, Dr. Carrie Simmons - GMFMC Peter Hood
Current stock exploitation status	Experiencing overfishing (2012)
Current stock biomass status	Overfished (2012)

Table 2.4.2. Specific Management Criteria

Note: mp = million pounds; gw = gutted weight.

Criteria	Current- 2011 Update Assessment (2012)		Proposed	
	Definition	Value	Definition	Value
MSST	$(1-M)*SSB_{MSY}$ $M=0.14$	1.529 trillion eggs	Value from the most recent stock assessment based on $MSST = [(1-M) \text{ or } 0.5 \text{ whichever is greater}] * B_{MSY}$	SEDAR 43
MFMT	F_{MSY}	0.269	F_{MSY} or proxy from the most recent stock assessment (median from probabilistic analysis)	SEDAR 43
MSY	F_{MSY}	0.269	Yield at F_{MSY} , landings and discards, pounds and numbers (median from probabilistic analysis)	SEDAR 43
F_{MSY}	F_{MSY}	0.269		
SSB_{MSY}	Equilibrium SSB @ F_{MSY}	2.094 trillion eggs	Spawning stock biomass (median from probabilistic analysis)	SEDAR 43
F Targets (i.e., F_{OY})	75% of F_{MSY}	0.202	75% F_{MSY}	SEDAR 43
Yield at F_{Target} (Equilibrium)	Equilibrium Yield @ F_{OY}		landings and discards, pounds and numbers	SEDAR 43
M		0.27	Natural Mortality, average across ages	SEDAR 43
Terminal F	Geometric mean 2008-2010	0.435	Exploitation	SEDAR 43
Terminal Biomass ¹	SSB_{2010}	1.345 trillion eggs	Biomass	SEDAR 43
Exploitation Status	$F_{CURRENT}/MFMT$	1.62	$F/MFMT$	SEDAR 43
Biomass Status ¹	$SSB_{CURRENT}/MSST$	0.64	$B/MSST$ B/B_{MSY}	SEDAR 43

Table 2.4.3. General projection information.

First Year of Management	2016 Fishing Year
Interim basis	- ACL, if ACL is met - Average exploitation, if ACL is not met
Projection Outputs	By stock and fishing year
Landings	pounds and numbers
Discards	pounds and numbers
Exploitation	F & Probability $F > MFMT$
Biomass (total or SSB, as appropriate)	SSB & Probability $SSB > MSST$ (and Prob. $SSB > B_{MSY}$ if under rebuilding plan)
Recruits	Number

Table 2.4.4. Base Run Projections Specifications. Long Term and Equilibrium conditions.

Criteria	Definition	If overfished	If overfishing	Not overfished, no overfishing
Projection Span	Years	$T_{Rebuild}$	10	10
Projection Values	$F_{Current}$	X	X	X
	F_{MSY} (proxy)	X	X	X
	75% F_{MSY}	X	X	X
	$F_{Rebuild}$	X		
	$F=0$	X		

NOTE: Exploitation rates for projections may be based on point estimates from the base run (current process) or the median of such values from the MCBS evaluation of uncertainty. The objective is for projections to be based on the same criteria as the management specifications.

Table 2.4.5. P-Star Projections. Short term specifications for OFL and ABC recommendations. Additional P-star projections may be requested by the SSC once the ABC control rule is applied.

Criteria		Overfished	Not overfished
Projection Span	Years	10	10
Probability Values	50%	Probability of stock rebuild	Probability of overfishing

The following should be provided regardless of whether the stock is healthy or overfished:

- OFL: yield at F_{MSY} (or $F_{30\% SPR}$ proxy)
- OY: yield at 75% for $F_{30\% SPR}$
- Equilibrium MSY and equilibrium OY

If the stock is overfished, the following should also be provided:

- F_{REBUILD} and the yield at F_{REBUILD} (where the rebuilding time frame is 10 years)
- A probability distribution function (PDF) that can be used along with the P^* selected by the SSC to determine ABC. If multiple model runs are provided, this may need to wait until the SSC selects which model run to use for management.
-

The SSC typically recommends OFL and ABC yield streams for 3-5 years out. Yield streams provided by assessment scientists should go beyond five years. If a 10-year rebuilding plan is needed, yield streams should be provided for 10 years.

Table 2.4.6. Quota Calculation Details

Note: mp = million pounds; ww = whole weight. ACT = annual catch target.

Current Quota Value (2014)	278000 lbs ww (ACT)
Next Scheduled Quota Change	2015
Annual or averaged quota?	Annual
Does the quota include bycatch/discard?	No- Landed only

Quotas are conditioned upon exploitation. Bycatch/discard estimates are considered in setting the quota; however, quota values are for landed fish only.

2.5. Management and Regulatory Timeline

Table 2.5.1. Annual Recreational Regulatory Summary

Note: Quota is in pounds whole weight.

Year	Quota	Season Open	Seasonal Closure	Season Close	Bag Limit	Size Limit	Effective Date(s):
1990 - 1996	N/A	Jan 1	None	Dec 31	None	None	Jan 1
1997 - 1998	"	Jan 1	"	Dec 31	Part of 20 reef fish aggregate limit	"	Jan 1
1999 - 2007	"	Jan 1	"	Dec 31	"	12" TL	Nov 1
2008	306000	Jan 1	"	Dec 31	"	14" FL	July 3
2009	356000	Jan 1	"	Dec 31	"	"	
2010 - 2011	405000	Jan 1	"	Dec 31	"	"	
2012	217100	Jan 1	"	June 10	"	"	May 14
2013	"	Jan 1	June 1 - July 31	Oct 14	2/person/day	"	June 10
2014	"	Jan 1	June 1 - July 31	Apr 30	2/person/day	"	

Notes:

- 1 Dates listed in "Season Open" or "Season Close" indicate days when fishing is still permitted
- 2 "Part of 20 reef fish aggregate bag limit" means up to 20 triggerfish could be kept per person with no other "reef fish" kept by the same person
- 3 Managed species: http://www.gulfcouncil.org/fishery_management_plans/Beta/GMFMCWeb/downloads/species%20managed.pdf

Table 2.5.2. Annual Recreational Regulatory Summary

Note: Quota is in pounds whole weight.

Year	Quota	Season Open	Seasonal Closure	Season Close	Trip Limit	Size Limit	Effective Date(s):
1990 - 1998	N/A	Jan 1	None	Dec 31	None	None	Jan 1
1999 - 2007	"	Jan 1	"	Dec 31	"	12" TL	Nov 1
2008	80000	Jan 1	"	Dec 31	"	14" FL	July 3
2009	93000	Jan 1	"	Dec 31	"	"	
2010	106000	Jan 1	"	Dec 31	"	"	
2011	106000	Jan 1	"	Dec 31	"	"	
2012	60900	Jan 1	"	June 30	"	"	May 14
2013	"	Jan 1	June 1 - July 31	Dec 31	12 fish/boat/day	"	June 10
2014	"	Jan 1	June 1 - July 31	Apr 30	12 fish/boat/day	"	

Notes:

- 1 Commercial longlining restricted to waters deeper than 50 fathoms west and 20 fathoms east of Cape San Blas as of Jan 1, 1990
- 2 Commercial longlining restricted to waters deeper than 35 fathoms from June 1 to August 31 as of May 26, 2010
- 3 Commercial longlining limited to 750 hooks per set beginning in 2010, with an extra 250 hooks in reserve on the boat as of May 26, 2010
- 4 "Season Open" or "Season Close" dates indicate permitted fishing days. "Seasonal Closure" dates indicate days when fishing is prohibited.
- 5 Commercial fish traps were phased out over 10 years beginning in March 1997, with all traps banned on Jan 1, 2006
- 6 Commercial/Recreational allocation split effective as of August 1, 2008

3. ASSESSMENT HISTORY AND REVIEW

Management of Gray Triggerfish (*Balistes capriscus*) in the U.S. Gulf of Mexico began in 1984 with the implementation of the Gulf of Mexico Fishery Management Council Reef Fish Fishery Management Plan. At that time, no formal assessment of the population dynamics of Gulf of Mexico Gray Triggerfish had been conducted. Gray Triggerfish is the only Balistid of 40 species of reef fish in the management unit. Two assessments of Gray Triggerfish were conducted in 2001 using different versions of a generalized Aggregated Surplus Production Model (ASPIC; Porch 2001; Valle et al. 2002). Based on the definition of MFMT ($F_{20\%SPR}$), both assessments indicated that the stock was overfished and undergoing overfishing. Fishing mortality rates were 65-70 % above sustainable levels. Biomass estimates were highly sensitive to parameter input restrictions, and all but one model run indicated that the stock had been severely overfished from the beginning of the time series. This was considered unrealistic as Gray Triggerfish was not a desirable target species. Additionally, the effect the 12-inch minimum size limit implemented in 1999 was unknown. Therefore, no new regulations were implemented based on the results of these assessments.

A benchmark stock assessment was completed in 2006 using an age-structured production model (SS-ASPM). The stock was determined to be undergoing overfishing but it was uncertain whether the stock was also overfished. Based on the definition of MFMT ($F_{30\%SPR}$), the reference fishing mortality was estimated to be 62% to high ($F_{2004}/MFMT = 1.62$). The review panel also examined a biomass based fishing mortality rate (F_{MSY}) but felt this measure was unacceptable because it was sensitive to the stock-recruitment relationship which was poorly estimated. The Review Panel stated that no conclusion could be made as to whether the stock was overfished, although it appeared to be approaching an overfished condition. Based on the definition of MSST ($SSB_{20\%SPR}$), the reference stock biomass was estimated to be slightly above MSST ($SSB_{2004}/MSST = 1.0$ to 1.2).

A SEDAR Update Assessment (UA) was conducted in 2011 to update the 2006 SEDAR-9 benchmark assessment of Gray Triggerfish within US waters of the Gulf of Mexico. Commercial and recreational fisheries statistical data, in addition to fishery independent data were updated through 2010. Any changes in data since the last benchmark assessment (SEDAR 9) were incorporated in the assessment. Fishery dependent and independent indices of abundance were constructed with updated data using the same methodology as in the benchmark assessment. The same age-structured production model used in SEDAR 9 (SS-ASPM) was applied to the update assessment. The final model used an average (rather than time varying) shrimp bycatch, incorporated an index of Gulf-wide shrimp effort, and used an updated age-length key and von Bertalanffy growth function. Results suggest that the stock was overfished and experiencing overfishing. As part of the 2011 update assessment, a statistical catch-at-age model (Stock Synthesis; SS) was evaluated as an alternative to SSASPM in an effort to characterize some of the potential error associated with the model fit and to determine if

SS could be used for future assessments. Model results were similar, despite differences in recruitment and historic fishery assumptions. Although management advice from the 2011 update assessment was based on the SS-ASPM model results, the SSC approved of the use of SS in future assessments.

As a result of concern over the effects on catchability of Gray Triggerfish of recently implemented regulations mandating the use of circle hooks in the reef fish fishery in the Gulf of Mexico, an analysis of the stock status controlling for this effect was conducted in 2013. Analysis of unpublished data indicated the implementation of circle hook regulations resulted in a 47% decrease in catchability of Gray Triggerfish, suggesting the stock was above levels estimated in 2011. However, the stock status did not change; therefore, the results were not used to develop new management advice.

1 Workshop Proceedings

1.1 Introduction

1.1.1. Workshop Time and Place

The SEDAR 43 Assessment Process for Gulf of Mexico Gray Triggerfish was conducted via a series of webinars held between February and June 2015.

1.1.2. Terms of Reference

1. Using data through 2013, provide a model consistent with the previous assessment configuration to incorporate and evaluate any recommended changes for this assessment.
2. Evaluate and document the following specific changes in input data or deviations from the benchmark model previous assessment model.
 - Review updated life history information (age and growth, mortality, and reproductive parameters)
 - Evaluate the effect of circle hooks on fishery dependent catch rates of gray triggerfish.
 - If warranted, incorporate a change in catchability and or selectivity due to the implementation of circle-hooks.
 - Review the stock recruitment relationship related to males only, females only, and males and females combined.

- *Evaluate the fishery-independent video and trap surveys conducted by NMFS Panama City Lab and FWRI.*
3. Document any revisions or corrections made to the model and input datasets, and provide updated input data tables. Provide commercial and recreational landings and discards in numbers and weight (pounds).
 4. Update model parameter estimates and their variances, model uncertainties, and estimates of stock status and management benchmarks. In addition to the base model, conduct sensitivity analysis to address uncertainty in data inputs and model configuration and consider runs that represent plausible, alternate states of nature.
 5. Project future stock conditions regardless of the status of the stock. Develop rebuilding schedules, if warranted. Provide the estimated generation time for each unit stock. Stock projections shall be developed in accordance with the following:

Scenarios to Evaluate (preliminary, to be modified as appropriate)

 1. Landings fixed at 2013 target.
 2. FOY= 75% FMSY (project when OY will be achieved)
 3. FREBUILD (if necessary)
 4. F=0 (if necessary)
 6. Develop a stock assessment report to address these TORs and fully document the input data, methods, and results.

1.1.3. List of Participants

Workshop Panel

Jeff Isely, Lead Analyst	NMFS Miami
Clay Porch	NMFS Miami
Mary Christman	MCC
Gary Fitzhugh	NMFS Panama City
Bob Gill	SSC
Dan Gothel	NMFS Miami
Adam Pollack	NMFS Pascagoula
Brooke Shipley-Lozano	SSC
Matthew Smith	NMFS Miami
Jim Tolan	SSC

Appointed Observers

Scott Hickman	Industry Representative
---------------------	-------------------------

Staff

Julie Neer	SEDAR
Ryan Rindone	GMFMC

Charlotte SchiaffoGMFMC

Additional Participants via Webinar

Robert Allman NMFS Panama City
 Neil Baertlein NMFS Miami
 Ken Brennan NMFS Beaufort
 Shannon Calay NMFS Miami
 Ching-Ping Chih NMFS Miami
 Michael Drexler Ocean Conservancy
 Doug DeVries NMFS Panama City
 Alisha Gray FWC
 Michael Larkin NOAA SERO
 Rich Malinowski NMFS SERO
 Vivian Matter NMFS Miami
 Kevin McCarthy NMFS Miami

 Ted Switzer FWC
 Adyan Rios NMFS Miami

1.1.4. List of Assessment Workshop Working Papers

Documents Prepared for the Assessment Process			
SEDAR43-WP-01	Validation of Annual Growth Zone Formation in Gray Triggerfish (<i>Balistes capriscus</i>) Dorsal Spines, Fin Rays, and Vertebrae	Robert J. Allman, Carrie L. Fioramonti, William F. Patterson III and Ashley E. Pacicco	10 March 2015
SEDAR43- WP -02	Oogenesis and fecundity type of Gray Triggerfish (<i>Balistes capriscus</i>) in the Gulf of Mexico	Erik T. Lang and Gary R. Fitzhugh	17 March 2015
SEDAR43- WP -03	Reproductive parameters of Gray Triggerfish (<i>Balistes capriscus</i>) from the Gulf of Mexico: sex ratio, maturity and spawning fraction	Gary R. Fitzhugh, Hope M. Lyon, and Beverley K. Barnett	17 March 2015
SEDAR43- WP -04	Length frequency distributions for gray triggerfish collected in the Gulf of Mexico from 1986 to 2013	Ching-Ping Chih	20 March 2015
SEDAR 43- WP -05	Standardized Catch Rate Indices for Gulf of Mexico Gray Triggerfish (<i>Balistes capriscus</i>) Landed During 1993-2013 by	Matthew W. Smith, Daniel Goethel, Adyan Rios, and Jeff	20 March 2015

	the Commercial Handline Fishery	Isely	
SEDAR 43- WP -06	Standardized Catch Rate Indices for Gulf of Mexico Gray Triggerfish (<i>Balistes capriscus</i>) Landed During 1986-2013 by the Headboat Fishery	Matthew W. Smith, Daniel Goethel, Adyan Rios, and Jeff Isely	20 March 2015
SEDAR 43- WP -07	Standardized Catch Rate Indices for Gulf of Mexico Gray Triggerfish (<i>Balistes capriscus</i>) Landed During 1981-2013 by the Recreational and Private Boat Fisheries	Matthew W. Smith, Daniel Goethel, Adyan Rios, and Jeff Isely	20 March 2015
SEDAR 43- WP -08	Indices of abundance for Gray Triggerfish (<i>Balistes capriscus</i>) from the Florida Fish and Wildlife Research Institute (FWRI) video survey on the West Florida Shelf	Kevin A. Thompson, Theodore S. Switzer, and Sean F. Keenan	24 March 2015
SEDAR 43- WP -09	Hook Selectivity in Gulf of Mexico Gray Triggerfish when using circle or 'J' Hooks	Alisha M. Gray and Beverly Sauls	25 March 2015
SEDAR 43- WP -10	Description of age data and estimated growth for Gray Triggerfish from the northern Gulf of Mexico: 2003-2013	Linda Lombardi, Robert Allman, and Ashley Pacicco	27 March 2015
SEDAR 43- WP -11	Gray Triggerfish Abundance Indices from SEAMAP Groundfish Surveys in the Northern Gulf of Mexico	Adam G. Pollack and G. Walter Ingram, Jr.	30 March 2015
SEDAR 43- WP -12	SEAMAP Reef Fish Video Survey: Relative Indices of Abundance of Gray Triggerfish	Matthew D. Campbell, Kevin R. Rademacher, Michael Hendon, Paul Felts, Brandi Noble, Michael Felts, Joseph Salisbury, and John Moser	30 March 2015
SEDAR 43- WP -13	Gray Triggerfish Ageing Error	Linda Lombardi	16 April 2015
SEDAR 43- WP -14	Gray triggerfish <i>Balistes capriscus</i> Findings from the NMFS Panama City Laboratory Trap & Camera Fishery-Independent Survey – 2004-2014	D.A. DeVries, C.L. Gardner, P. Raley, and W. Ingram	21 April 2015

1.1.5. Workshop Presentations

Presentations Prepared for the Assessment Process

SEDAR43- In-person Workshop Intro Presentation	SEDAR 43 Gulf of Mexico Gray Triggerfish Standard Assessment Data and Assessment Workshop	Jeff Isely	10 March 2015

1.1.6. List of Assessment Workshop Supplementary Papers

Workshop Supplementary Documents			
SEDAR43-RD-01	Recruitment of Age-0 Gray Triggerfish to Benthic Structured Habitat in the Northern Gulf of Mexico	Carrie M. Simmons and Stephen T. Szedlmayer	9 December 2014
SEDAR43- RD -02	Territoriality, reproductive behavior, and parental care in gray triggerfish, <i>Balistes capriscus</i> , from the northern Gulf of Mexico	Carrie M. Simmons and Stephen T. Szedlmayer	9 December 2014
SEDAR43- RD -03	Description of reared preflexion gray triggerfish, <i>Balistes capriscus</i> , larvae from the northern Gulf of Mexico	Carrie M. Simmons and Stephen T. Szedlmayer	17 March 2015

1.2 Panel Recommendations and Comments on Terms of Reference

Term of Reference 1: *Using data through 2013, provide a model consistent with the previous assessment configuration to incorporate and evaluate any recommended changes for this assessment.*

The Panel recommended the use of a fully integrated age and length based statistical-catch-at-age model (Stock Synthesis) as the modeling platform. The model configuration and data inputs are described in Section **Error! Reference source not found.**

Term of Reference 2: *Evaluate and document the following specific changes in input data or deviations from the benchmark model previous assessment model.*

- *Review updated life history information (age and growth, mortality, and reproductive parameters)*
- *Evaluate the effect of circle hooks on fishery dependent catch rates of gray triggerfish.*
- *If warranted, incorporate a change in catchability and or selectivity due to the implementation of circle-hooks.*

- Review the stock recruitment relationship related to males only, females only, and males and females combined.
- Evaluate the fishery-independent video and trap surveys conducted by NMFS Panama City Lab and FWRI.

All changes to the data following the Data and Assessment Workshop are reviewed in Section **Error! Reference source not found..**

Term of Reference 3: Document any revisions or corrections made to the model and input datasets, and provide updated input data tables. Provide commercial and recreational landings and discards in numbers and weight (pounds).

Section **Error! Reference source not found.** provides a complete description of all data inputs. Appendix A includes the input data file used in the SEDAR 43 Gray Triggerfish Stock Synthesis model.

Term of Reference 4: Update model parameter estimates and their variances, model uncertainties, and estimates of stock status and management benchmarks. In addition to the base model, conduct sensitivity analyses to address uncertainty in data inputs and model configuration and consider runs that represent plausible, alternate states of nature.

Estimates of assessment model parameters and their associated standard errors are reported in 3.1.4 and Table 3.1.1. Results of the sensitivity analyses are characterized in Section 3.1.7, Table 3.2.4 - Table 3.2. 6, and Figure 3.2. 67 - Figure 3.2. 76. Model convergence was tested by varying starting parameters and refitting the model (Table 3.1.3). Uncertainty in the assessment parameters and estimated values is characterized in Section 3.2.2 and Table 3.2.1. Sensitivity analyses are presented in Section 3.2.7. Estimates of stock biomass, spawning stock biomass, recruitment, and fishing mortality are presented in Table 3.2.2 - Table 3.2 3.

Term of Reference 5: Project future stock conditions regardless of the status of the stock. Develop rebuilding schedules, if warranted. Provide the estimated generation time for each unit stock. Stock projections shall be developed in accordance with the following:

Scenarios to Evaluate (preliminary, to be modified as appropriate)

1. Landings fixed at 2013 target.
2. FOY= 75% FMSY (project when OY will be achieved)
3. FREBUILD (if necessary)
4. F=0 (if necessary)

Projected stock status is presented in section 3.2.9.

Term of Reference 6: Develop a stock assessment report to address these TORs and fully document the input data, methods, and results.

This report satisfies this Term of Reference.

2 Data Review and Update

The following list summarizes the main data inputs used in the assessment model:

Life history

- Age and growth
- Natural mortality
- Maturity
- Fecundity

Landings

- Commercial (combined vertical line, longline and trap): 1945-2013, East and West Gulf
- Recreational (combined headboat, charterboat and private): 1945-2013, East and West Gulf

Discards

- Commercial (combined vertical line, longline and trap): 2000-2013, East and West Gulf
- Recreational (combined headboat, charterboat and private): 1981-2013, East and West Gulf
- Shrimp Bycatch: 1945-2013

Length composition of landings (Converted to Age Comp with annual ALKs)

- Commercial (combined vertical line, longline and trap): 1990-2013, East and West Gulf
- Recreational (combined headboat, charterboat and private): 1981-2013, East and West Gulf

Abundance indices

Fishery-independent

- SEAMAP Groundfish (Trawl): 1987-2013
- SEAMAP Larval Survey: 1986-2013
- Combined video: 1993-1997, 2001-2002 & 2004-2013

Fishery-dependent

- Commercial Handline: 1993-2007, East and West Gulf
- Recreational Charterboat and private (MRFSS): 1981-2013, East Gulf
- Recreational Headboat: 1986-2013, East and West Gulf
- Shrimp Bycatch (as an effort series): 1945-2013

Discard mortality

- Commercial fleets, East and West Gulf
- Recreational fleets, East and West Gulf

A brief summary of each input will be provided in the following sections.

2.1 Life history

2.1.1 Age and growth

SEDAR43-WP-01 described the validation of annual growth increments in Gray Triggerfish dorsal spines, fin rays and vertebrae. The aging structures were marked with oxytetracycline (OTC). After 262 days, the fish were sacrificed, and the hard parts were extracted and sectioned. One translucent zoned formed distal to the OTC mark on all aging structures during winter. Additional fin rays and vertebrae with corresponding dorsal spines were sampled during fishery-independent surveys to compare translucent zone counts between hard parts. There was a significant difference in translucent zone counts between fin ray and dorsal spine sections ($t_{1,25} = -3.15$, $P = 0.004$), with fin ray counts being on average 1 zone higher than dorsal spines. Translucent zone counts in vertebrae were similar to those counted in dorsal spines with no significant difference between structures ($t_{1,57} = 1.90$, $P = 0.062$). The combined results of

this study validate annual translucent zone formation in Gray Triggerfish hard parts, with dorsal spines being considered the most reliable ageing structure.

The growth of Gray Triggerfish was summarized in SEDAR43-WP-10. Gray Triggerfish were sampled for age structure (using dorsal spines) from both the recreational and commercial fisheries in the Gulf of Mexico. According to this study, Gray Triggerfish were fully recruited to the commercial fishery by 4-6 years of age, while younger fish were landed by the recreational fishery. Fish became rare in both fisheries by age 10. Several size-modified von Bertalanffy growth models that accounted for non-random sampling due to minimum-size restrictions were examined. The data/assessment working group recommended a combined-sex growth model with a constant coefficient of variation at age (CV = 0.22) and the following von Bertalanffy parameters (**Figure 2.1.1**):

$$\begin{aligned}L_{inf}(\text{cm FL}) &= 58.97 \\K(\text{year}^{-1}) &= 0.14 \\t_0(\text{year}) &= -1.66\end{aligned}$$

The CV as a function of length at age, the asymptotic length (L_{inf}), the von Bertalanffy growth coefficient (k) and the theoretical age at length zero (t_0), were fixed within the SS model.

Meristic relationships were also provided to the Data/Assessment Workshop. The parameters describing these relationships are summarized in **Table 2.1.1**.

2.1.2 Natural mortality

The Data/Assessment Workshop developed an estimate of natural mortality-at-age using the Lorenzen (1996) estimator, and a target M estimated using Hoenig (1983) assuming a maximum age of 15 years. The resulting natural mortality vector (**Table 2.1.2** and **Figure 2.1.2**) was fixed within the assessment model. The previous assessment (SEDAR 9) used a fixed natural mortality rate equal to 0.27 which is also shown in **Figure 2.1.2**.

2.1.3 Maturity

The reproductive parameters of Gray Triggerfish, sex ration, maturity and spawning fraction were described in SEDAR43-WP-03. Based upon histological preparations of ovary sections, females displaying vitellogenic or more advanced oocytes (yolked oocytes) were defined as “mature” (consistent with prior SEDARs). Females with cortical alveoli (CA) or primary growth oocytes (PG) as the leading stage, but displaying atretic-yolked oocytes, were classified as “uncertain maturity”. Females with primary growth oocytes and with no indications of prior spawning were classified as “immature”. Female records used to determine maturity were taken only from the reproductive period (June, July and August).

In order to expand the number of maturity observations, especially among the smallest and youngest fish, macroscopic maturity records were added for consideration. Similar to the criteria above, only records from June, July and August from scientific surveys were retained. Macroscopic classes (Lang et al. 2013) include immature, maturing, running ripe, spent and inactive. Gray Triggerfish records listed as maturing, running ripe and spent were aggregated and considered “mature”, while females scored as inactive were considered to have “uncertain maturity”.

Specimens were assigned 50 mm fork length classes and the proportion mature was related to length classes (mid-point) using logistic regression weighted by the numbers in each length class. Females considered to be “uncertain” in histological or macroscopic staging were censored while immature and mature totals were retained. A logistic model, based upon the Gompertz function was fitted to the data using maximum likelihood (logistic regression). Age at 50% maturity (A_{50}) was 1.5 years for females (**Figure 2.1.3**). This maturity function was assumed fixed in the SS model.

2.1.4 Sex Ratio

The sex ratio for Gray Triggerfish in the GOM was slightly female dominated; 56% female based upon histology and 64% female based upon macroscopic observation (SEDAR43-WP-03). However, studies that sampled Gray Triggerfish from commercial sources in the Gulf tended to report higher ratios of males overall and at larger sizes. Therefore, for the purposes of the SS model, the sex ratio was fixed at 50% female for all ages.

2.1.5 Fecundity

The oogenesis and fecundity of Gray Triggerfish was described in SEDAR43-WP-02. The study objective was to verify the pattern of oogenesis and fecundity type. From 1999-2012, 1092 female Gray Triggerfish were collected from the eastern Gulf of Mexico with subsets used to calculate condition indices and assess ovarian histology. Gonadosomatic and hepatosomatic indices and Fulton’s condition factor indicated liver and somatic energy stores increased prior to spawning and were depleted throughout the spawning period. This is characteristic of a capital pattern of energy storage and allocation to reproduction.

Typical of a capital pattern, the authors observed a hiatus in oocyte size distribution and group synchronous oogenesis, both traits of a deterministic fecundity type. However, evidence that fecundity was not set prior to spawning included the observation of “de novo” vitellogenesis during the spawning season; secondary oocytes increased in number and failed to increase in mean size over time. Thus Gray Triggerfish are thought to exhibit an indeterminate fecundity type with mixed reproductive traits that may characterize species exhibiting female parental care in warm water environments.

Using oocyte growth rate and the proportion of females bearing postovulatory follicles, the inter-spawning interval was estimated to range from 8-11 d. This indicated production of 8-11 batches per female may occur during an estimated 86-d reproductive period. Batch fecundity (BF) ranged from 0.34 to 2.0 million eggs and was significantly related to fork length (FL): The Data/Assessment Workshop recommended a power-function fit to batch fecundity at length to model female reproductive potential (**Figure 2.1.4**).

$$\text{Batch Fecundity} = 51.357 * \text{Fork Length(mm)}^{2.8538}$$

2.2 Landings

2.2.1 Commercial landings

Commercial landings statistics from 1963-2013 were obtained from the NMFS Accumulated Landings System (ALS). The eastern and western regions were separated at approximately the mouth of the

Mississippi River. The eastern region included NMFS statistical shrimp areas 1-12 and the western region included areas 13-21. Several gears were combined under the designation “Handline” (aka vertical line) including electric reel, bandit rig, manual reel and manual handline.

Commercial landings were reviewed at the Data/Assessment Workshop and are presented in **Table 2.2.1** and in **Figure 2.2.1**. A few significant updates to the commercial landings have taken place since the previous assessment (SEDAR 9 Update). These updates affected the landings estimates for 1989-1993, and 2008. The updated values are indicated by gray highlighting in **Table 2.2.1**.

Commercial landings (lbs whole weight) were reported by gear, and include handline, longline, trap, and ‘other’. As in the previous assessment (SEDAR 9 Update), landings by commercial gears were combined within each region (i.e. Eastern U.S. Gulf of Mexico and Western U.S. Gulf of Mexico). Landings were dominated by commercial handline. A trap fishery existed for a period, but has since been eliminated by regulation. Although Gray Triggerfish are caught on bottom longline, these catches are limited to the Eastern U.S. Gulf of Mexico and Gray Triggerfish are not the targeted species. Landings reported under ‘other’ made up less than 1% of overall commercial landings. The aggregated commercial landings were converted to metric tons whole weight for input into the SS model (**Table 2.2.1b**). Landings prior to 1963 were estimated. Commercial landings were assumed to have a standard error of 0.05.

2.2.2 Recreational landings

The recreational fishery statistics for gray triggerfish were obtained from three separate sampling programs: Marine Recreational Information Program (MRIP), Texas Parks and Wildlife Department (TPWD) and the Southeast Region Headboat Survey (SRHS). MRIP (formerly known as MRFSS) began in 1979 (data prior to 1981 are generally considered less reliable), and collects estimates of shore based, charter boat and private/rental boat fishing from Florida through Louisiana. MRIP also included information from headboat trips from 1981-1985. MRIP collects information on fish landed, discarded dead and released alive. However, it is important to note that estimates of discards and released fish are self-reported.

The SRHS focuses on monitoring and sampling the recreational headboat fisheries in the Atlantic and Gulf of Mexico, from Texas to Florida. SRHS data collection includes catch records from every trip and biological samples from dockside intercepts by port samplers.

Prior to 1986, TPWD was responsible for reporting landings from all recreational boat modes operating in Texas. However, since 1986 GOM headboat landings have been compiled by the SRHS. TPWD continued to sample charterboat and private boat fishing modes, but the emphasis was placed on sampling bay and inshore fishing effort. Therefore, it is likely that offshore fishing is under-represented in the TPWD estimates. TPWD also does not record information on discards.

Recreational landings (in numbers of fish) were reviewed by the Data/Assessment Workshop and are presented in **Table 2.2.2** and **Figures 2.2.2 - 2.2.3**. Recreational landings are available by mode and include headboat, charterboat, private boat, and shore. Prior to 1981, private and charterboat landings are only available as a single combined mode. Between 1946 and 1980, the combined private and charterboat mode landings are estimated from effort data using a constant catch per effort ratio.

Landings by headboat, charterboat and private modes were pooled within geographic area (East, West). Landings reported for the shore mode were excluded as they comprised <1% of overall recreational landings. Recreational landings were assumed to have a standard error of 0.05.

2.3 Discards

2.3.1 Commercial discards

Commercial discards are available by gear for handline (aka vertical line), longline and trap; however, only handline estimates were used. Handline discards reviewed at the Data/Assessment Workshop were re-estimated after evaluating the reliability of the logbook effort data used in the discard calculation. That alternative method of estimating discards was:

$$\left(\frac{\text{observer reported Gray Triggerfish discard rate}}{\text{observer reported Gray Triggerfish kept rate}} \right) \times \text{Gray Triggerfish landings}$$

Discards were calculated for each year/region/season. Calculated discards across strata within each year and region were summed to obtain yearly regional total discards (**Table 2.3.1**).

Strata were:

Year

Region (east = statistical zones 1-8, west = 9-21)

Season (red snapper season – open or closed)

For the SS model, the annual proportion discarded was used rather than the absolute magnitude of discards. These proportions are illustrated in **Figure 2.3.1**. Discard estimates are available since 2005. Landings and discard estimates are derived from mandatory self-reported logbooks.

2.3.2 Recreational discards

Annual estimates of recreational discards were derived from MRIP for the years 1981-2013. Discards are based on dockside interviews (intercepts) of anglers and represent the self-reported number of fish discarded alive.

The recreational discards were reviewed at the Data and Assessment Workshop and are presented in **Table 2.3.2**. Estimated recreational discards are available by mode for headboat, charterboat, private boat, and shore. Discards by headboat, charterboat, and private modes were used in the assessment model. The discards from the shore mode were excluded. Recall that landings from this mode made up less than 1% of overall recreational landings.

For the SS model, the annual proportion discarded was used rather than the absolute magnitude of discards. These proportions are illustrated in **Figure 2.3.2**.

2.4 Age composition of landings

2.4.1 Age composition of commercial landings

Estimated commercial age composition was derived using the observed length frequency and annual age-length keys. The effective sample size for the derived age composition was assumed to be equal to the annual number of aged fish sampled from commercial trips (**Table 2.4.1**). The derived commercial age composition is summarized in **Figures 2.4.1**. Cohorts are not readily apparent in the commercial data (**Figure 2.4.1**). This may be due to the weak relationship between length and age, and the use of annual ALKs to derive age composition from length frequency data.

2.4.2 Age composition of recreational landings

Estimated recreational age composition was also derived using the observed length frequency and annual age-length keys. The effective sample size for the derived age composition was assumed to be equal to the annual number of aged fish sampled from recreational trips (**Table 2.4.1**). It should be noted that the number of aged fish was quite small in some years, particularly for the private fishery (**Table 2.4.1**). Data for the charterboat and private modes were aggregated into a single combined mode. The derived commercial age composition is summarized in **Figure 2.4.1**. Like the commercial age composition, cohorts are also not readily apparent in the recreational data (**Figure 2.4.1**). This may be due to the weak relationship between length and age, and the use of annual ALKs to derive age composition from length frequency data.

2.4.3 Age composition of shrimp bycatch

After initial attempts to estimate annual age composition using the length composition of the SEAMAP groundfish survey and shrimp observer program yielded unreliable results, characterized by anomalously old fish, the previous assessment (SEDAR 9 Update) assumption was retained. Because the SEDAR 9 panels found no basis for extracting separate age classes from the single peak in length frequency observed during the fall groundfish survey, that assessment assumed that the shrimp bycatch was dominated by age 0s with minor error due to contamination by older fish. Likewise, shrimp bycatch was assumed to be composed of age-0 Gray Triggerfish in this assessment (**Figure 2.4.2**).

2.5 Measures of population abundance

Indices of abundance were presented and considered during the Data/Assessment Workshop. The eight indices of abundance that were recommended for use in the assessment include:

Fishery-independent (3)

SEAMAP Groundfish (Trawl): 1987-2013

SEAMAP Larval Survey: 1986-2007

Combined video: 1993-1997, 2001-2002 & 2004-2013

Fishery-dependent (5)

Commercial Handline (vertical line): 1993-2013, East and West Gulf

Recreational Charterboat/Private (MRFSS): 1981-2013, East Gulf

Recreational Headboat: 1986-2013, East and West Gulf

Seven of eight recommended indices were also used in the previous assessment (SEDAR9 Update-AR). The combined video survey index (SEAMAP VIDEO, Panama City Video, and FWRI Video) is a new index that delivers a longer time series than the SEAMAP Video alone by standardizing the three similar

fishery-independent video surveys across common habitat types. Development, review and incorporation of this index in the assessment satisfies the fifth element of Term of Reference 2.

Three of the eight indices were derived from fishery-independent data sources: the SEAMAP fall groundfish survey, SEAMAP Larval survey and the combined video survey (**Table 2.5.1** and **Figures 2.5.1 – 2.5.3**). The SEAMAP groundfish index was derived as the mean number of Gray Triggerfish caught per trawl hour. The combined video survey was derived as the minimum count of Gray Triggerfish (maximum number of individuals in the field of view at one instance) per 20 minute recording.

There were five recommended fishery-dependent indices: the Eastern Gulf Marine Recreational Fishery Statistic Survey (MRFSS-East) index, the Eastern and Western Gulf Southeast Regional Headboat Survey indices (SRHS-East, SRHS-West), and the Eastern and Western Gulf Commercial Vertical Line indices, (**Tables 2.5.2 - 2.5.3** and **Figures 2.5.4 – 2.5.8**). The SERHS index was derived using numbers of Gray Triggerfish landed per angler hour and the MRFSS index, which represents the charterboat and private modes, was derived using the numbers of Gray Triggerfish landed or discarded per angler hour. The commercial vertical line index was derived as pounds of Gray Triggerfish landed per hook hour.

For input into the Stock Synthesis assessment model, the coefficients of variation (CV) associated with the standardized indices were converted to log-scale standard errors as follows:

$$\log(SE) = \sqrt{\log_e(1 + CV^2)}$$

The relative shrimp effort series 1945-2013 was also fit in the model in a manner similar to the fit of the CPUE series. The relative shrimp effort and associated log-scale variance are illustrated in **Figure 2.5.9**.

2.6 Discard Mortality

Discard mortality of gray triggerfish has not been extensively studied. This topic was discussed at the Data/Assessment Workshop. Based on a review of best available information, the panel recommended a 5% discard mortality rate for use in the SEDAR 43 assessment model. The panel further recommended the evaluation of a 10% mortality rate as a sensitivity analysis.

2.7 Tables

Table 2.1.1. Meristic regressions for gray triggerfish (2003-2013) from the Gulf of Mexico. Data combined from all data sources, both fishery independent and dependent. Length Type: Max TL – Maximum Total Length, FL – Fork Length, Nat TL – Natural Total Length, SL – Standard Length. Weight Type: G WT – Gutted Weight, W WT – Whole Weight. Units: length (mm) and weight (kg). Linear and non-linear regressions calculated using R (lm and nls functions, respectively).

Regression	Equation	statistic	N	Data Range
Max TL to FL	$FL = \text{Max_TL} * 0.791 + 21.282$	$r^2=0.9754$	818	Max TL: 110 – 753; FL: 109 – 572
Nat TL to FL	$FL = \text{Nat_TL} * 0.807 + 24.360$	$r^2=0.9539$	130	Nat TL: 65 – 712; FL: 65 – 617
SL to FL	$FL = \text{SL} * 1.153 + 10.311$	$r^2=0.9946$	391	SL: 87 – 440; FL: 109 – 515
SL to Max TL	$\text{Max_TL} = \text{SL} * 1.425 - 5.687$	$r^2=0.9769$	388	SL: 87 – 440; Max TL: 110 – 622
Max TL to W WT	$W\ WT = 3.679 \times 10^{-08} * (\text{max_TL}^{2.842})$	RSE = 0.1398	374	Max TL: 155 – 585 ; W WT: 0.067 – 3.380

2.8 Figures

Figure 2.1.1 Von Bertalanffy growth relationship recommended by the Data Workshop (dark blue) compared to alternative models including the model used in SEDAR9 Update (light blue). The von Bertalanffy parameters assuming constant CV with length were: L_{inf} = 58.97cm FL, K = 0.14, and t_0 = -1.66.

Figure 2.1.2 Recommended age-specific natural mortality vector recommended by the Data/Assessment Workshop (red line). The target mortality based on Hoenig et al. (1983) was 0.28 (green line). The previous assessment (SEDAR9 Update) assumed a fixed mortality rate of 0.27 (blue line).

Figure 2.1.3 Proportion mature at age.

Figure 2.1.4 Batch fecundity at length.

Figure 2.2.1 Gray Triggerfish commercial landings from the Eastern (top panel) and Western (bottom panel) U.S. Gulf of Mexico in pounds whole weight from 1963-2013.

Figure 2.2.2 Gray Triggerfish recreational landings (numbers of fish) from the U.S. Gulf of Mexico from 1945-2013. Values prior to 1981 are estimated.

Figure 2.2.3 Detail of Gray Triggerfish recreational landings (numbers of fish) from the U.S. Gulf of Mexico from 1945-2013 by area and mode.

Figure 2.3.1 Gray Triggerfish commercial discards from the U.S. Gulf of Mexico as a proportion of total catch from 2000-2013.

Figure 2.3.2 Gray Triggerfish recreational discards from the U.S. Gulf of Mexico as a proportion of total catch (ab1b2) from 1981-2013.

Figure 2.4.1 Annual derived age composition data of Gray Triggerfish landed by the commercial and recreational fisheries in the Eastern and Western U.S. Gulf of Mexico.

Figure 2.4.2 Annual age composition assigned to Gray Triggerfish discarded as bycatch in the shrimp fishery in the U.S. Gulf of Mexico.

Figure 2.5.1. Standardized indices of abundance and the associated log-scale standard errors from the Gulf of Mexico fall plankton (larval) survey in the U.S. Gulf of Mexico. The index is scaled to a mean of one over the time series and was derived using the number of Gray Triggerfish per trawl hour.

Figure 2.5.2 Standardized indices of abundance and the associated log-scale standard errors from the Gulf of Mexico fall SEAMAP groundfish trawl survey in the U.S. Gulf of Mexico. The index is scaled to a mean of one over the time series and was derived using the number of Gray Triggerfish per trawl hour.

Figure 2.5.3 Standardized indices of abundance and the associated log-scale standard errors from the Gulf of Mexico combined SEAMAP, Panama City and FWRI video survey. The index is scaled to a mean of one over the time series and was derived using the minimum count (maximum number of individuals in the field of view at one instance) of Gray Triggerfish per 20 minute recording.

Figure 2.5.4 Standardized indices of abundance and the associated log-scale standard errors from the Gulf of Mexico MRFSS survey in the Eastern U.S. Gulf of Mexico. The index is scaled to a mean of one over the time series and was derived using the number of Gray Triggerfish per angler hour.

Figure 2.5.5 Standardized indices of abundance and the associated log-scale standard errors from the Eastern Gulf of Mexico headboat recreational fishery. The index is scaled to a mean of one over the time series and was derived using the number of Gray Triggerfish per angler hour.

Figure 2.5.6 Standardized indices of abundance and the associated log-scale standard errors from the Western Gulf of Mexico headboat recreational fishery. The index is scaled to a mean of one over the time series and was derived using the number of Gray Triggerfish per angler hour.

Figure 2.5.7 Standardized indices of abundance and the associated log-scale standard errors from the Eastern Gulf of Mexico vertical line commercial fishery. The index is scaled to a mean of one over the time series and was derived using the pounds of Gray Triggerfish per number of hook hours.

Figure 2.5.8 Standardized indices of abundance and the associated log-scale standard errors from the Western Gulf of Mexico vertical line commercial fishery. The index is scaled to a mean of one over the time series and was derived using the pounds of Gray Triggerfish per number of hook hours.

Figure 2.5.9 Relative Gulf of Mexico shrimp effort and the associated log-scale standard errors during 1945-2013. The effort index is scaled to a mean of one over the time series.

3 Stock assessment models and results

3.1 Stock Synthesis

3.1.1 Overview

The primary assessment model selected for the Gulf of Mexico Gray Triggerfish assessment was Stock Synthesis version 3.24S (Methot 2013). Stock Synthesis (SS) has been widely used and tested for assessment evaluations, particularly in the US west coast NMFS centers. Descriptions of SS algorithms and options are available in the SS user's manual (Methot 2013) and in Methot and Wetzel (2013).

Stock Synthesis is an integrated statistical catch-at-age model which is widely used for stock assessments in the United States and throughout the world (Methot and Wetzel 2013). SS takes relatively unprocessed input data and incorporates many important processes (mortality, selectivity, growth, etc.) that operate in conjunction to produce estimates of observed catch, size and age composition and CPUE indices. Because many inputs are correlated, the concept behind SS is that they should be modeled together. This helps to ensure that uncertainties in the input data are properly accounted for in the assessment. SS is comprised of three sub-models: 1) a population sub-model that recreates an estimate of the numbers/biomass at age using estimates for various natural processes such as natural mortality, growth, fecundity, etc.; 2) an observational sub-model that consists of observed (measured) quantities from the population such as relative abundance (i.e., CPUE) or the proportion of individuals at length/age; and 3) a statistical sub-model that employs a likelihood framework to quantify the fit of the observations to the recreated population.

3.1.2 Data sources

The data sources used in the assessment model are described in Section 2. **Figure 3.1.1** summarizes the data sources and their corresponding temporal scale. The Stock Synthesis data file is included as Appendix A.

3.1.3 Model configuration and equations

Life history

The growth parameters were estimated externally from the SS model assuming a single combined sex von Bertalanffy model (**Figure 2.1.1**, SEDAR43-WP-10). The parameterization of the von Bertalanffy model in SS included two additional parameters used to describe the variability in size-at-age. These parameters represent the coefficient of variability (CV) in size-at-age at the minimum (age 1) and at the maximum (age 10) observed ages. Models testing the variance structure were compared; these assumed either constant standard deviation at age, constant CV at age, linear increase in CV with age, or linear increase in CV with length. AIC results indicated that assuming a constant CV of 0.2039 with length best described the data.

Within SS, growth is modeled with a three parameter von Bertalanffy equation (L_{min} , L_{max} , and K). In SS, when fish recruit at the real age of 0.0 they have a body size equal to the lower limit of the first population bin (L_{bin}). Fish then grow linearly until they reach a real age equal to the input value of A_{min}

(0.5 years) and have a size equal to the L_{min} (28.3 cm). As they age further, they grow according to the von Bertalanffy growth equation. L_{max} was specified as equivalent to L_{inf} (58.97 cm). The three parameters of the von Bertalanffy equation (L_{min} , L_{max} , and K) were fixed in the SS model (**Table 3.1.1**). The CVs for length-at-age were input using a fixed parameter of 0.204 for all ages (**Table 3.1.1**). A fixed length-weight relationship was used to convert body length (cm) to body weight (kg) (**Table 3.1.1**).

The natural mortality rate (M) was assumed to decrease as a function of age based on a Lorenzen (2005) function. The Data/Assessment Workshop life history working group initially recommended using $M = 0.27$ for scaling the Lorenzen curve (consistent with SEDAR9 UPDATE). However, when using the Hoenig (1983) function to estimate M based on a maximum age of 19, the estimated base mortality rate was 0.28. This revised base M value was then used to develop the age-specific natural mortality vector input into SS as a fixed vector (**Table 2.1.2**). **Figure 2.1.2** illustrates the base age-specific natural mortality M values and the two M at age sensitivity vectors considered during the SEDAR 43 Gray Triggerfish evaluation.

Gray Triggerfish fecundity was modeled as batch fecundity (Figure 2.1.4). The SEDAR 43 life history working group indicated that the relationship between batch fecundity and age was weak and recommended using the relationship between batch fecundity and length.

Stock-recruitment model

The Beverton-Holt stock-recruitment function was used in this assessment to characterize the stock-recruitment (S-R) relationship. Three parameters of the S-R relationship were estimated in the model; the log of unexploited equilibrium recruitment $\log(R_0)$, an offset parameter for initial equilibrium recruitment relative to virgin recruitment $\log(R_1)$, and the steepness (h) parameter. The steepness parameter describes the fraction of the unexploited (virgin) recruits produced at 20% of the equilibrium spawning biomass level. A fourth parameter representing the standard deviation in recruitment (σ_R) was also estimated.

Annual deviations from the stock-recruit function were estimated for an early period (prior to 1981) and a later data-rich period (1982-2012). The data-rich period is associated with the beginning of collection of annual composition data (e.g., length, age). The SS model has the ability to track cohorts through time, so it was assumed that the age composition data provided some indication of trends in recruitment between 1965 and 1981. Prior to 1965, recruitment was estimated directly from the S-R relationship. Stock Synthesis assumes a lognormal error structure for recruitment. Therefore, expected recruitments were bias adjusted. Methot and Taylor (2011) recommend that the full bias adjustment only be applied to data-rich years in the assessment (i.e., 1982-2013) when there is sufficient data to inform the model about the full range of recruitment variability. Full bias adjustment was used from 1982 to 2012. Bias adjustment was phased in linearly from no bias adjustment to full bias adjustment from 1965-1981. Bias adjustment was phased out over the last year, decreasing from full bias adjustment to no bias adjustment.

Initial Model Starting conditions

The beginning year of the SS assessment model was 1945. Minor removals of Gray Triggerfish are assumed to have occurred in the Gulf of Mexico prior to 1945; however, for this evaluation the stock was assumed to be at equilibrium at the start of the model. Model runs starting in 1881 were presented at the Data/Assessment Workshop. The assessment panel recommended the incorporation of data back only to 1945 for use in the base model, consistent with the previous assessment (SEDAR 9 Update).

Fleet structure and indices of abundance

The assessment model includes five fishing fleets. The fleets include the aggregated recreational headboat, charterboat and private modes in the Eastern and Western U.S. Gulf of Mexico (Recreational East, Recreational West), the aggregated commercial handline, longline and trap fisheries in the Eastern and Western U.S. Gulf of Mexico (Commercial East, Commercial West), and the bycatch of Gray Triggerfish in the shrimp fishery in the Gulf of Mexico (Shrimp Bycatch). Gray triggerfish as bycatch in the shrimp fishery was considered to be a 100% dead discard fishery; however, a negligible amount of landed catch was input to meet model requirements (i.e. 100 fish annually). The previous assessment used the same primary fleets, but shrimp fishery bycatch was modeled as if it were a directed harvest of age-1 equivalent fish.

The assessment model included eight indices of abundance, as described in Section 2. The commercial and headboat indices were modeled as retained landings indices. The MRFSS East index of abundance included discards in the estimation, and as such was treated as an index of total catch. The three fishery-independent indices were also assumed to model total catch. An index of shrimp effort was also fit as an effort series.

Selectivity and retention distributions

Fleet-specific age based selectivity and retention patterns, and the assumed discard mortality rates are illustrated in Figures 3.1.2 – 3.1.5.

Age-based selectivity functions were specified for all fleets and indices. Selectivity patterns characterize the probability of capture-at-age for a given gear and are used to model not only gear selectivity, but also fishery availability (due to spatial patterns of fish and fishers). Most of the age-based selectivity functions used in the Gray Triggerfish assessment were modeled using double normal functions. The double normal function is described by two adjacent normal distributions. Each has its own variance term and the two are joined by a horizontal line. This selectivity pattern is described by six parameters, all of which were estimated in the SS model. The selectivity of the shrimp fishery was fixed at 1.0 for age-0, and 0.0 for all other ages. This fishery was assumed to discard all Gray Triggerfish, and a 100% mortality rate was applied. Selectivity of the combined video index was modeled as a 2-parameter logistic function. The larval index was assumed to represent the adult spawning biomass, therefore the selectivity pattern was fixed to the assumed biomass at age of mature fish.

Selectivity patterns were assumed to be constant over time for each fishery and survey. However, the Gray Triggerfish fishery has experienced changes in management regulations over time. These were assumed to influence retention patterns more so than selectivity. As such, these changes were

accounted for in the model by the incorporation of time-varying retention patterns and modeling discards explicitly.

Regulatory management changes include the implementation of a 12 inch fork length (30.48 cm FL) size limit from 1999 until 2007 across all fleets. The size limit was increased to 14 inches TL (35.56 cm FL) in 2008. Retention patterns were assumed to change with the changes in the size limit. Retention is modeled as a logistic function with size in SS. Four parameters describe this function; the inflection point, the slope, the asymptote and the male offset inflection (not applicable to this model). The retention patterns associated with the 1999-2007, and 2008-2013 time blocks were assumed to be knife-edge at the size limit. The retention pattern for the pre-1999 time block for all fleets was a fixed, knife-edge relationship at the 6 inch FL size limit (minimum size of retained fish in the landings). Retention above the size limit was freely estimated to account for discards due to factors unrelated to minimum size restrictions (e.g. bag limits).

3.1.4 Estimated parameters

A total of 478 parameters were used for the base case model, and of these 410 were estimated. (Table 3.1.1). The estimated parameters included three (3) parameters used to define the S-R Relationship (h , R_0 , sR), 345 fleet-specific fishing mortality rates, 28 used to estimate selectivity and retention, 33 used to estimate annual recruitment deviations, and one (1) used to estimate initial catchability coefficient for the shrimp fleet.

Table 3.1.1 includes SS predicted parameter values and their associated standard errors, initial parameter values, and minimum and maximum values a parameter could take. Parameters designated as fixed were held at their initial values. Parameter bounds were selected to be sufficiently wide to avoid truncating the searching procedure during maximum likelihood estimation. The soft bounds option in SS was utilized when fitting the assessment model. This option creates a weak symmetric-beta penalty on selectivity parameters to move parameters away from the bounds (Methot 2013).

3.1.5 Model Convergence

Model convergence was evaluated using a jitter analysis. The jitter analysis perturbs the initial values so that a broad range of parameter values along the likelihood surface are used as starting values. This exercise is typically used to confirm that the model converged to a global solution rather than a local minima. Starting values of all estimated parameters were randomly perturbed by 10% and the model was run for 100 trials. All 100 trials converged on a single solution (**Table 3.1.2**). While this test cannot prove convergence of the model, evidence suggests the base model configuration is stable.

3.1.6 Uncertainty and Measures of Precision

Uncertainty in parameter estimates and derived quantities was evaluated using multiple approaches. First, uncertainty in parameter estimates was quantified by computing asymptotic standard errors for each parameter (**Table 3.1.1**). Asymptotic standard errors are calculated by inverting the Hessian matrix (i.e., the matrix of second derivatives of the likelihood with respect to the parameters) after the model

fitting process. Asymptotic standard errors are based upon the analytical estimate of the variance near the converged solution.

Likelihood profiles were also completed for three key model parameters of the stock – recruitment function: steepness of the stock-recruit relationship (h), the log of unexploited equilibrium recruitment (R_0), and the variation in recruitment (σ_R). Likelihood profiles are commonly used to elucidate conflicting information among various data sources, to determine how asymmetric the likelihood surfaces surrounding point estimates may be, and to provide an additional evaluation of how precisely parameters are being estimated.

3.1.7 Sensitivity analysis

Uncertainty in data inputs and model configuration were also examined through sensitivity analyses. The sensitivity models reported in this section are not meant to be a comprehensive evaluation of all possible aspects of model uncertainty, nor do they reflect the full range of models considered in developing the base case. These scenarios are intended to provide information about sensitivity of model results (e.g., spawning stock biomass, recruitment, fishing mortality) to assumptions regarding key model parameters. The order in which they are presented is not intended to reflect their importance; each run included herein provided important information for developing or evaluating the base case model and alternate states of nature.

Discard Mortality

Discard mortality in the model was fixed at 5% based on recommendations by the SEDAR 43 Data Workshop panel. A discard mortality rate of 10% was evaluated as a sensitivity run.

Circle Hook Change in Catchability

Based on an evaluation of data provided by Shipp et al. (unpublished data), the effect of a regulation requiring the use of circle hooks in the reef fish fishery in the Gulf of Mexico was estimated to reduce catchability of Gray Triggerfish by a factor of 2.14 (i.e. CPUE on J hooks/CPUE on circle hooks = 2.14). The change in catchability was modeled by adjusting the CPUE series for all hook-and-line fisheries (recreational east, recreational west, commercial east, commercial west) accordingly. Sensitivities were evaluated assuming 1) no effect and 2) 2X the estimated effect (4.28).

Suspect headboat index values

Starting in 2009, a decrease in estimated CPUE of approximately 90% in the headboat fishery in the Western U.S. Gulf of Mexico was observed (**Figure 2.5.6**). Although this decrease coincides with the implementation of an increase in size limit, a decrease in bag limit and a mandatory gear change to circle hooks, a similar decrease in estimated CPUE was not observed for either the Eastern Gulf recreational index or the Western Gulf commercial index. Extensive investigation of headboat catch and effort data failed to find a correlation between the drop in CPUE and any other factor. To determine the sensitivity of the model results to these unusual estimates, a sensitivity run excluding index values from 2009-2012 in the Western Gulf Headboat Index was evaluated.

Retention

Anecdotal information suggests that Gray Triggerfish are not highly prized by some recreational and commercial fisherman and are sometimes discarded at sizes above the minimum size limit. Therefore, the proportion retained above the size limit was estimated within the base model and sensitivity runs fixing the proportion retained above the size limit at 80% were also evaluated.

Index Inclusion (Jack-knife analysis)

The final set of sensitivity runs was used to evaluate the model sensitivity to each of the indices of abundance. A jack-knife approach was used where each index of abundance was removed from the model and then the model was refit to the remaining data.

3.1.8 Retrospective analysis

A retrospective analysis was conducted to assess the consistency of stock assessment results by sequentially eliminating a year of data from the terminal year while retaining the same model configuration. The results of this exercise are useful in assessing potential biases in the estimates of key SS derived quantities (e.g., stock biomass, fishing mortality, recruitment) and uncertainty in terminal year estimates.

3.1.9 Projection Methods

For the purpose of projecting stock status and associated yields, the base assessment model was re-estimated allowing for correlated recruitment deviations. No other parameters were changed from the base configuration. Analysis of recruitment deviations indicated that strong correlation existed in recruitment and suggested that the inclusion of a correlation parameter in the model could improve the deviation estimates, particularly the terminal year estimate which was considered highly suspect (**Table 3.1.1**).

Using the model that allowed for correlated recruitment deviations, projections were run for a low recruitment scenario. Deterministic low recruitment projections were accomplished by calculating the average recruitment deviation over the last ten data years (1994 – 2013) and applying the result to the recruitment estimates for the first five projection years (2014 – 2018). After the first five years, all future recruitments were determined solely by the stock recruitment relationship and not bias corrected or adjusted via a recruitment deviation to account for recent trends.

Projections were done using 2015 as the terminal data year (i.e., 2016 was the first year for which caps and allocations could be set. The average of the 2011, 2012, and 2013 fleet specific exploitation rates fixed as the exploitation rates for 2014 and 2015, for which the actual data was not yet available. Annual and equilibrium OFL values were obtained from projections of F_{SPR30} . ABC values are preliminary and were calculated using a target of SPR30, a rebuilding year of 2025 and a p^* value of 0.427. Uncertainty in forecasted yields and stock status was accounted for using model estimated standard errors.

3.2 Model Results

3.2.1 Measures of model fit

Landings

Landings were assumed to have a standard error of 0.05. The predicted landings fit the observed landings nearly identically (**Figures 3.2.1 - 3.2.4**).

Discards

The SS model was fit to the discard fractions estimated for the four directed fleets: Rec E, Rec W, Com E, Com W (**Figures 3.2.5 – 3.2.8**). The model was also fit to the estimated GOM Shrimp Bycatch in absolute numbers (**Figure 3.2.9**). As discards are considered to be known with low precision, they were modeled as the median of the time series with a CV=0.1. As the annual estimates were thought to be less reliable than the mean, the discard fractions and discards were modeled using a “Super-Year” approach. This capability allows the user to introduce data that may best represent an amalgam across a number of contiguous years. The model will then estimate a single expected value for these observations over the same time period.

The fractions of Gray Triggerfish discarded by the recreational fisheries were modeled in three time blocks to account for various fishing regulations. The observed and predicted discard fractions from the recreational east fleet show an increasing trend roughly corresponding to regulatory changes (**Figure 3.2.5**). The model overestimated the recreational east fleet discard fractions in years prior to regulations (before 1999) and also underestimated discards following the most recent regulation change of 2008 (**Figure 3.2.5**). However, in general the fit to the discard fractions is acceptable. Similarly, the observed and predicted discard fractions from the recreational west fleet also show an increasing trend roughly corresponding to regulatory changes (**Figure 3.2.6**). However the observed annual discards rates were more variable between years. The model fit to the observed recreational west discard fractions was generally acceptable (**Figure 3.2.6**).

The annual fractions of Gray Triggerfish discarded by the commercial fisheries were modeled in two time blocks. Observed commercial discard fractions increased following regulatory changes in 2008 in both the eastern and western commercial fleets. The model overestimated discard fractions in the 2000-2007 time period and underestimated discard fractions during 2008-2013 (**Figures 3.2.7 and 3.2.8**). However, given the substantial coefficient of variation, the fits were acceptable.

Discards of Gray Triggerfish from the shrimp fishery were modeled in two time blocks. The first time block incorporated years prior to 1972 when effort was estimated, and years following 1971 when effort was based on a survey. The use of time blocks for shrimp discards reduced the effect of imprecision in the model. Observed discards from the shrimp fishery showed large variation during the second time block. The SS fit to the discards was generally adequate (**Figure 3.2.9**).

Indices of abundance

The SS model was fit to five fishery-dependent indices, three fishery-independent indices and an effort series. The fits to the indices are summarized in **Figures 3.2.10 – Error! Reference source not**

found. **3.2.18.** The model fit to the recreational east standardized index (RMSE = 0.445) suggests a decrease in the abundance of relevant age-classes since a peak in 1989 (Figure 3.2.10). The standardized index also exhibits a general decrease during this time period; however, the model underestimates a recent increase in the standardized index between 2008 and 2013.

The SS model fit to the SRHS (Headboat) East standardized index (RMSE = 0.229) indicates a decrease in the indexed age-classes after 1989, slightly earlier than the observed peak in the index in 1990 (**Figure 3.2.11**). The standardized index also suggests a general decrease during this time period; however, the model failed to fit a recent decrease in the standardized index between 2008 and 2013. The contradictory trends in the MRFSS East and SRHS (Headboat) East indices since 2008 quite likely contributed to the poor SS model fit for both indices. MRFSS East contains discards, and consequently references somewhat younger fish. This could partially explain the discrepancy.

The model fit to the recreational west standardized index (RMSE = 0.914) also shows a decrease in the index since a peak in 1989 (**Figure 3.2.12**). However, the standardized index demonstrates a substantial decrease from 1991-2000, then an increase from 2000-2005 followed by a sharp decline in 2008. The model fitted trend was relatively flat compared to the observed series. The contradictory trends between the eastern and western recreational indices could have contributed to this lack of fit.

The model fit to the standardized commercial east index (RMSE = 0.282) and standardized commercial west index (RMSE = 0.458) are shown in **Figures 3.2.13** and **3.2.14**. The model fit to the commercial east index generally followed the trend in the index. The model fit to the commercial west index appears to be relatively flat, missing observed changes in the index. In addition, the model failed to fit the recent decline in CPUE between 2011 and 2013. However, given the estimated high variance in the index, the lack of fit in the SS estimated index is not unexpected.

The SS model fit to the Shrimp Fishery effort series was very close (RMSE = 0.066) (Figure 3.2.15). This is a common characteristic of SS models that fit to effort series, and likely results from the underlying model specifications.

The SS model fits to the standardized fishery-independent indices are shown in **Figures 3.2.16- 3.2.18**. The standardized SEAMAP Larval Survey was used as an index of spawning biomass, and varies annually without overall trend. Although the model fit suggests recent declines in the spawning biomass, the fit to the observations was poor overall (Figure 3.2.16), in part due to the large coefficients of variation. The standardized SEAMAP Fall Groundfish (Trawl) Survey index is thought to reference young of the year Gray Triggerfish (**Figure 3.2.17**). Like the SEAMAP larval survey, it was also highly variable with large CVs. The index suggested higher than average recruitment in 1991 and 2001, and a generally declining trend since 2001. The fit to this index was relatively poor, with a generally flat trend and a substantial residual pattern. The standardized combined video index (**Figure 3.2.18**) suggests a declining trend since 1994. Like the SEAMAP Groundfish Index, the model fit to the combined video index was poor, with a generally flat trend and a substantial residual pattern.

Derived Age Composition

The model fits to the derived age composition associated with the landings series, and the corresponding Pearson residuals are presented in **Figures 3.2.19 – 3.2.28**. In general, the SS model fit the derived age comps well across all fleets, as reflected by Pearson residual values generally less than four units.

The fits to the recreational east derived age composition were quite good (**Figure 3.2.19 and 3.2.20**). In general, the predicted and observed distributions were nearly identical in most years. The slight degradation in the fits during the most recent years suggests that anglers may have responded to regulatory changes in length and bag limits in a manner that differed somewhat from model predictions. Pearson residuals indicate that there is little systematic noise in the model fit to the data.

The fits to the recreational west derived age composition were also quite good (**Figures 3.2. 21 - 3.2.22**). The predicted and observed distributions were nearly identical in most years. The model has routinely overestimated the abundance of older age classes somewhat since 2009, the year following a change in regulations. Pearson residuals indicate a slight temporal bias as younger age classes were overestimated from 1994-2003 and underestimated thereafter.

The fits to the commercial east derived age composition were somewhat less strong (**Figures 3.2.23 – 3.2.24**). The predicted and observed distributions were similar in most years, except the earliest which were characterized by relatively low effective sample sizes. The model frequently overestimated or underestimated the numbers of individuals in the most dominant age class. However, the Pearson residuals suggest that there was little systematic noise in the model fit to the data for this fleet.

The fits to the commercial west derived age composition were relatively good (**Figure 3.2 25 – 3.2.26**). The predicted and observed distributions were quite similar in all years except 2010 and 2011. The model overestimated the abundance of older age classes in these years. Because the model was constrained to discard sub-legal size fish, the lack of fit to these years could be a function of commercial landings that contained either sub-legal or faster growing fish. Regardless, Pearson residuals indicate that there as little systematic noise in the model fit to the data for this fleet.

All Gray Triggerfish discarded from the shrimp fishery were assumed to be age-0, and selectivity was fixed at 1.0 for age-0, and 0.0 for all other ages. Thus, as expected, the model fit exactly to the assumed age composition of the shrimp fishery (**Figures 3.2. 27 – 3.2.28**).

3.2.2 Parameter estimates and associated uncertainty

Table 3.1.1 summarizes the parameter estimates and the asymptotic standard errors from SS. The majority of parameters have relatively low standard errors. The parameters with larger standard errors are mainly the age selectivity parameters and some years of the recruitment deviations

Likelihood profiles were generated for several key parameters in this assessment. They include three parameters in the Beverton-Holt stock-recruitment function: steepness (h), recruitment at an unexploited state, $\ln(R0)$, and the offset in recruitment from the unexploited equilibrium, $\ln(R1_offset)$. Likelihood profiles were used to evaluate how estimable these parameters were, and to identify possible conflicts in the signal derived from various data inputs.

The likelihood profile of the steepness parameter shows that there were possible conflicts between data sources (**Figure 3.2.29**). The age, survey and recruitment components exhibited similar likelihood patterns. The discard component favored a lower steepness. Steepness was relatively insensitive to catch. The model run with steepness fixed at 0.6 reached an alternative solution, likely the result of the starting value, and should be excluded from consideration of steepness.

The total likelihood component from the $\ln(R_0)$ likelihood profile indicates that the global solution for this parameter is approximately 9.5 (**Figure 3.2.30**). The recruitment likelihood component is the largest component of the total dictating this outcome. The data conflicts are seemingly minimal.

The likelihood profile on the parameter accounting for the variation in recruitment (σ_R) suggests that the dominant influence on the likelihood is the age component (**Figure 3.2.31**). Survey and discard components favored lower σ_R , and the model was insensitive to catch.

3.2.3 Selectivity and retention

Age-based selectivity functions were estimated for all fleets and indices. Selectivity patterns represent the probability of capture-at-age for a given gear and are used to model not only gear selectivity but also fishery availability (due to spatial patterns of fish and fishers). Selectivity patterns were assumed to be constant over time for each fishery and survey (**Figures 3.2.33 – 3.2.41**). The Gray Triggerfish fisheries have experienced changes in management regulations over time. These were assumed to influence the retention patterns more so than selectivity. As such, these changes were accounted for in the model using time-varying retention patterns and by modeling discards explicitly.

Changes in the management regulations for all fleets include the implementation of a 12 inch fork length (30.48 cm FL) size limit from 1999 until 2007. The size limit was increased to 14 inches TL (35.56 cm FL) in 2008. Retention patterns were assumed to vary with the changes in the size limit (**Figures 3.2.42 – 3.2.45**). The asymptotic parameters for the retention functions (i.e., the proportion retained above the size limit) were estimated for all fleets, and are summarized in **Table 3.1.1**. The proportion retained above the size limit varied from 0.564 in the recreational west fleet to 0.698 in the commercial east fleet.

The fishery-independent surveys age selectivity patterns were fixed based on either observed or assumed age composition. All Gray Triggerfish in the SEAMAP larval survey were assumed to be age 0. The SEAMAP fall groundfish survey was used as a proxy of spawning stock biomass in the previous year; therefore, all ages were assumed to be captured. The video survey selectivity pattern was estimated externally based on the probability of detection at size and was then fixed in the model to be essentially asymptotic.

3.2.4 Recruitment

The three key parameters for defining the stock-recruitment relationship were steepness (h), virgin recruitment (R_0), and $\sigma(R)$. All three parameters were estimated without priors and were estimated within the upper and lower bounds (**Table 3.1.1**). Steepness was estimated at 0.459 for the base model. The log of virgin recruitment is estimated at 9.76. The $\sigma(R)$ parameter was estimated at 0.358.

The plot of the stock-recruitment relationship shows unusually high recruitment associated with years 1986 and 1987 (Figure 3.2.26). The model is driven to estimate these high recruitments in order to account for the large increase in landings in the mid-1980s in the recreational east and west fishing fleets (**Figures 3.2.1 and 3.2.2**). In general, levels of recruitment are positively related to spawning biomass values, suggesting a relatively strong stock-recruit relationship. This is an unusual result for Gulf of Mexico assessments, and may be influenced by nest-guarding behavior in Gray Triggerfish. Recall that the likelihood profile on steepness supported estimates between 0.4 and 0.45, but also exhibited unusual behavior at steepness values greater than 0.45 (**Figure 3.2.29**).

Predicted age-0 recruits are presented in **Figure 3.2.47**, and in **Table 3.2.1**. Average recruitment was variable over time. Higher average recruitments are generally preceded and followed by relatively lower than average recruitments. The RMSE for recruitment deviations was 0.264. Recruitment in 1985 was predicted to be the highest recruitment over the time series with a secondary peak observed in 1999. Age 0 recruitments during the six most recent years were predicted to be relatively low.

3.2.5 Stock biomass

Predicted total biomass and spawning output in eggs are summarized in **Table 3.2.1** and **Figures 3.2.48 – 3.2.49**. Total biomass has generally decreased throughout the time series. The decreasing trend seen in total biomass is also evident in the predicted spawning output time-series.

The predicted numbers-at-age and mean age is presented **Figure 3.2.50**. The predicted numbers-at-age suggest two strong recruitment events in 1985 and 1999. Mean age has varied between one and two between 1945 and 2013. Mean age was relatively constant between 1945 and 1981, but declined rapidly through 1986. Mean age has shown a gradual increase since 2000, likely the result of regulations limiting harvest, and/or lower than average recruitment.

The trend in the numbers-at-length and mean length is obviously similar to the predicted numbers-at-age and mean age (**Figure 3.2.51**). Although mean age and mean size have not changed considerably over the time series, it is important to note that the relative proportion of larger and older fish has declined steadily.

3.2.6 Fishing mortality

The predicted fishing mortalities (overall and by fleet) are presented in **Table 3.2.2** and **Figure 3.2.52 – 3.2.54**. Predicted total fishing mortality declined, on average, between 1989 and 2013, although the 2013 fishing mortality increased somewhat over 2012.

The main source of directed fishing mortality is the recreational east fleet (**Figures 3.2.53 – 3.2.54**). The recreational west fleet accounts for the next highest fishing mortality. Although the commercial east and west fleets exhibited some significant fishing pressure in the early 1990s, fishing mortality due to commercial fishing has remained low in recent years. The trend in fishing mortality associated with shrimp fishery bycatch mirrors effort for that fleet. It appears to be quite significant because it takes a significant fraction of the age-0 fish (but no other age-classes are affected).

3.2.7 Sensitivity analyses

The results of the sensitivity analyses are summarized in **Table 3.2.3** and **Figures 3.2.55 – 3.2.60**.

Discard mortality

The primary assessment results were relatively insensitive to an increase in discard mortality (to 10%) as shown in Figures 3.2.55 - 3.2. 57.

Circle Hook Change in Catchability

Sensitivities were evaluated to explore the sensitivity of model results to assumptions regarding the circle-hook effect on catchability (base = 2.14 fold reduction in q , sensitivities at 2X assumed effect and no effect). The model was sensitive to the removal of the circle hook effect. The removal of the circle hook adjustment reduced SSB, recruitment and total biomass by over 40% (**Figures 3.2.55 - 3.2. 57**)

Suspect headboat index values

Starting in 2009, a decrease in CPUE of approximately 90% in the headboat fishery in the Western U.S. Gulf of Mexico was observed. Although this decrease coincided with the implementation of an increase in size limit, a decrease in bag limit and a mandatory gear change to circle hooks, a similar decrease in CPUE was not observed in either the Eastern Gulf recreational indices or the Western Gulf commercial index. Extensive investigation of headboat catch and effort data failed to find a correlation between the drop in CPUE and any other factor. A sensitivity run excluding index values from 2009-2012 in the Western Gulf Headboat Index was evaluated. The exclusion of SRHS West index values since 2008 caused an increase in estimates of SSB, recruitment and total biomass (**Figures 3.2.55 - 3.2. 57**).

Retention

Anecdotal information suggests that Gray Triggerfish are not highly prized by some fisherman and are sometimes discarded at sizes above the minimum size limit. The proportion retained above the size limit was estimated in the base model resulting in retention estimates that ranged from 50-65% by fleet. A sensitivity run with retention fixed at 90% was included for comparison. Using a fixed retention of 90% had very little effect on the outcome of the analysis (**Figures 3.2.55 - 3.2. 57**).

Jack-knife of indices

The results of the sensitivity exercise to evaluate index inclusion (i.e., jack-knife analysis) are summarized in **Figures 3.2.58-3.2.60** and **Table 3.2.4**. The model was most sensitive to exclusion of the SRHS West and SEAMAP Larval indices. The fit to these indices was similar when comparing the RMSEs.

3.2.8 Retrospective results

The results from the retrospective analysis are summarized in **Figures 3.2.61 and 3.2.62**. There were no major patterns or systematic biases in the spawning stock biomass. The scale of SSB did vary between years, but the direction was inconsistent. However, a retrospective pattern in age-0 recruits was evident

(Figure 3.2.62), suggesting that recruitment estimates were sensitive to the effective terminal year of the data.

3.2.9 Benchmark and reference points

Stock status measures for the base and sensitivity runs are presented in Table 3.2.3. The results indicate that Gray Triggerfish have been overfished since 1993, as spawning stock biomass has remained below MSST (SPR30) since that time.

3.2.10 Projections

SS estimated the stock recruitment correlation parameter to be 0.729 (Table 3.2.5). Documentation for the exact interpretation and implementation of this parameter in the estimation process is limited. However, this value is similar to a one year auto-correlation value estimated independently of SS and was assumed to have a similar interpretation in SS. Patterns in the estimated recruitment deviations were similar to those obtained in the base model (Tables 3.1.1 and 3.2.5) with the exception of the terminal year deviation which was estimated to be -0.52 with correlation instead of -0.12 without.

Near term overfishing limits for gray triggerfish were around one million pounds retained whole weight while the ABC values calculated with a 2025 rebuild timeline and a p^* of 0.427 were approximately 200,000 pounds in the near term (Table 3.2.6). Optimum yield projections effectively reduced the harvest rates of the directed fleets by 75% however the retained yield estimates obtained by SS were uniformly higher than 75% because of the contribution of the shrimp fishery which did not experience harvest rate reductions in the optimum yield run (Table 3.2.7).

Stock Rebuilding times vary widely depending on the projection scenario used (Table 3.2.8). Under the low recruitment scenario, rebuilding is slow and doesn't begin to accelerate until several years after the negative recruitment deviations are removed and the larger cohorts reach sexual maturity. Rebuilding time estimates are based on the assumption that gray triggerfish will experience lower than average recruitment through 2018 and average recruitment from then on. Rebuilding times will increase or decrease if the future recruitment pattern differs greatly from the one assumed.

3.2.11 Discussion

The assessment model predicts that total biomass and the spawning potential (egg production) have generally decreased throughout the time series, and are currently estimated near (or at) the lowest annual value (Figures 3.2.48 and 3.2.49). Although spawning stock biomass recovered somewhat between 1995 and 2002, the stock biomass continued to decline thereafter. Despite a decline in fishing mortality in all fleets since 2003 (Figure 3.2.52 – 3.2.54), the stock has shown little sign of recovery.

The Gray Triggerfish fishery is dominated by recreational fishing in the Eastern U.S. Gulf of Mexico. Despite regulations to reduce bag limits and increase size limits, the species has not exhibited sustained recovery. Two standardized indices of abundance were associated with the recreational east fleet: the MRFSS East index and the SRHS East survey. Although the MRFSS East index shows a consistent increase in CPUE since 2008, the SRHS East survey shows a consistent decrease during the same period. Consequently, the model integrates the signals of both indices resulting in a low but relatively stable

spawning stock estimates. The SRHS West survey also showed a substantial decrease in CPUE beginning in 2009. Since, the MRFSS West index was rejected by the DW Panel. The result is that the recent low CPUE estimates from the SRHS in the West are not buffered (or exacerbated) by other recreational indices in that region. However, the relatively low contribution of this fishery to total landings likely reduces the influence of this index on the stock trends.

3.2.12 Recommendations

1. Evaluate existing methods for deriving historical discard numbers and discard rates and improve methods as appropriate.
2. Develop/evaluate methods to maintain continuity of fishery-dependent indices in light of management regulations.
3. Develop a relationship between catchability of Gray Triggerfish on circle hooks when compared to J hooks.
4. Identify underlying factors resulting in discrepancies between recent estimates of cpue between the MRFSS Index and the SRHS Index.
5. Explore separating fisheries by gear, rather than by area.
6. Identify factors resulting in the release of fish in excess of size limits and improve estimates of asymptotic retention.

3.3 Acknowledgements

Many people from state and federal agencies assisted with assembling the data included in this stock assessment. The Data and Assessment Workshop Panel was incredibly helpful with addressing issues and nuances of the data. The Panel was also instrumental in guiding the stock assessment model configuration. The author would also like to acknowledge two internal reviews who made significant improvements to this report.

Table 3.2.6 Overfishing limits (OFL; retained yield in millions of pounds whole weight) for long-term equilibrium runs and acceptable biological catch (ABC; retained yield in millions of pounds whole weight) for a 2025 target rebuilding date. OFL was calculated as the median (50th percentile) of the probability density function of retained yield (millions of pounds). Target spawning potential ratio (SPR) values were achieved over the last ten years of the model (i.e., assumed equilibrium; 2065-2074) where the average SPR over that time frame equaled the target value. Equilibrium yield was the average OFL over the last ten years. Equilibrium optimal yield (OY) was the average retained yield over the last ten years with $F_{\text{Direct}} = 0.75 * F_{\text{Direct at SPRtarget}}$ for the directed fisheries. ABC was calculated using a P^* of 0.427 (the 42.7th percentile) of the probability density function of retained yield obtained from the projection of F_{Rebuild} (the harvest rate that achieves the specified gulfwide SPR in 2025). A P^* of 0.427 implies a 42.7% probability of overfishing in any given year **Projections assume 2014 and 2015 catch was fixed at the average of the 2011, 2012, and 2013 catch.**

	OFL (Million Pounds)	ABC (Million Pounds)
Year	SPR 30%	SPR 30%
2016	1.05	0.21
2017	0.99	0.21
2018	0.96	0.22
2019	0.94	0.22
2020	0.93	0.23
2021	0.96	0.24
2022	1.08	0.28
2023	1.19	0.32
2024	1.29	0.36
2025	1.37	0.40
Equil	2.23	0.77
Equil OY	2.10	NA

Table 3.2.7 Retained yield and relative fishing mortality for optimal yield (OY) runs where the directed fishing mortality was equivalent to 0.75 multiplied by the F at SPR 30% (from equilibrium OFL calculations). Proportions are given as the OY run value divided by the SPR 30% run value. Harvest rate is total removals (in weight) divided by total biomass. Retained yield is in millions of pounds. Equilibrium values are averages over the last ten years (2065-2074) of the projection. **Projections assume 2014 and 2015 catch was fixed at the average of the 2011, 2012, and 2013 catch.**

Optimal Yield (OY) Run Results				
Year	OFL/Retained Yield (mp)	Yield Proportion	Harvest Rate	Harvest Rate Proportion
2016	0.81	0.77	0.13	0.85
2017	0.79	0.79	0.13	0.86
2018	0.78	0.81	0.13	0.86
2019	0.77	0.82	0.16	0.88
2020	0.77	0.83	0.14	0.88
2021	0.80	0.84	0.14	0.87
2022	0.91	0.84	0.14	0.87
2023	1.02	0.85	0.15	0.86
2024	1.11	0.86	0.15	0.86
2025	1.20	0.87	0.15	0.86

Table 3.2.8 The time required to rebuild based on the projection year that SSB_{proxy} is achieved for SPR 30%. F=0 runs indicate the time to rebuild in the absence of any fishing mortality. **Projections assume 2014 and 2015 catch was fixed at the average of the 2011, 2012, and 2013 catch.**

SPR	F=0		OFL (Reach SPR by 2074)		ABC 2025 (Reach SPR by 2025)	
	SSB	MSST	SSB	MSST	SSB	MSST
0.3	2023	2021	2070	2031	2025	2022
