#### Abstract

The Southeast Fisheries Science Center Mississippi Laboratories (MSLABS) has conducted standardized bottom longline surveys in the Gulf of Mexico, Caribbean, and Western North Atlantic Ocean since 1995. Additionally in 2011, the Congressional Supplemental Sampling Program (CSSP) was conducted, where high levels of standardized bottom longline survey effort were maintained from April through October. Data from the MSLABS Bottom Longline Survey and the CSSP Survey were used to produce a relative abundance index for Sandbar Shark. The abundance trend was generally flat from 1995-2008. Beginning in 2009 there was a large increase in the relative abundance that has continued through 2015.

## Introduction

The Southeast Fisheries Science Center (SEFSC) Mississippi Laboratories (MSLABS) has conducted standardized bottom longline (BLL) surveys in the Gulf of Mexico (GOM), Caribbean, and Western North Atlantic Ocean (Atlantic) since 1995. The objective of these surveys is to provide fisheries independent data for stock assessment purposes for as many species as possible. These surveys are conducted annually in U.S. waters of the GOM and/or the Atlantic, and provide an important source of fisheries independent information on sharks, snappers and groupers. The evolution of these surveys has been the subject of many documents [e.g., Ingram et al. 2005 (LCS05/06-DW-27)] and was not described again in this document.

In 2011, the Congressional Supplemental Sampling Program (CSSP) was conducted, where high levels of survey effort were maintained from April through October (for a full review of the CSSP see Campbell et al. 2012). This program was conducted using the same gear as the annual bottom longline survey and a similar survey design. The only difference was the CSSP sampled out to 400 m , whereas, the annual survey samples to a depth of 366 m . The purpose of this document is to provide an abundance index for Sandbar Shark (Carcharhinus plumbeus).

## Methodology

## Survey Design

Details concerning methodologies and evolution of the NMFS BLL have been covered in previous documents (most recently LCS05/06-DW-27) and will not be repeated in this document. Basic sample design was a proportional allocation of stations based on continental
shelf width within statistical zones and stratified by depth ( $50 \%$ allocation $9 \mathrm{~m}-55 \mathrm{~m}, 40 \%$ allocation $55 \mathrm{~m}-183 \mathrm{~m}, 10 \%$ allocation $183 \mathrm{~m}-366 \mathrm{~m}$ ). When the survey began in 1995, Jhooks were the standard gear. Over time a change was made to $15 / 0$ circle hooks. However, Henwood et al. (2005) examined the difference in catch rates between the two hooks types and found no significant difference in catch rates for Sandbar Sharks.

## Data

Data for the annual BLL survey was obtained from the SEFSC MSLABS Shark Unit and the CSSP data was obtained from SEFSC MSLABS Information Technology Unit. Data from the CSSP was used to fill in gaps in the annual bottom longline survey due to vessel breakdowns and weather delays in 2011. As to not over represent any one area of the GOM, data from the August survey was used for the Eastern GOM, while data from September was used for the Western and Central GOM. These time frames historically match up with when the annual BLL survey sampled those areas. For this document, the combined dataset will be hereafter referred to as NMFS BLL.

## Data Exclusions

We used the time series of data between 1995 and 2015 to develop Sandbar Shark abundance indices (Table 1). Depth was used to limit the data, with no stations deeper than 183 m being included, since there were no records of Sandbar Sharks being caught any deeper. In 2005, additional sampling was done in October and November (43 stations) since most of the survey was canceled due to Hurricane Katrina. However, there was little temporal overlap in other years ( 17 stations in 2004), so all stations done outside of June, July, August and September were removed. After limiting the data, 3,767 stations were used in the analysis.

## Index Construction

Delta-lognormal modeling methods were used to estimate relative abundance indices for Sandbar Shark (Pennington, 1983; Bradu \& Mundlak, 1970). The main advantage of using this method is allowance for the probability of zero catch (Ortiz et al. 2000). The index computed by this method is a mathematical combination of yearly abundance estimates from two distinct generalized linear models: a binomial (logistic) model which describes proportion of positive abundance values (i.e. presence/absence) and a lognormal model which describes variability in only the nonzero abundance data (cf. Lo et al. 1992).

The delta-lognormal index of relative abundance $\left(I_{y}\right)$ was estimated as:
(1) $I_{y}=c_{y} p_{y}$,
where $c_{y}$ is the estimate of mean CPUE for positive catches only for year $y$, and $p_{y}$ is the estimate of mean probability of occurrence during year $y$. Both $c_{y}$ and $p_{y}$ were estimated using generalized linear models. Data used to estimate abundance for positive catches (c) and probability of occurrence ( $p$ ) were assumed to have a lognormal distribution and a binomial distribution, respectively, and modeled using the following equations:

$$
\begin{equation*}
\ln (c)=X \beta+\varepsilon \tag{2}
\end{equation*}
$$

and

$$
\begin{equation*}
p=\frac{e^{\mathbf{X} \beta+\varepsilon}}{1+e^{\mathbf{X P}^{\beta}+\varepsilon}}, \tag{3}
\end{equation*}
$$

respectively, where $c$ is a vector of the positive catch data, $p$ is a vector of the presence/absence data, $X$ is the design matrix for main effects, $\beta$ is the parameter vector for main effects, and $\varepsilon$ is a vector of independent normally distributed errors with expectation zero and variance $\sigma^{2}$. Therefore, $c_{y}$ and $p_{y}$ were estimated as least-squares means for each year along with their corresponding standard errors, $\mathrm{SE}\left(c_{y}\right)$ and $\mathrm{SE}\left(p_{y}\right)$, respectively. From these estimates, $I_{y}$ was calculated, as in equation (1), and its variance calculated using the delta method approximation

$$
\begin{equation*}
V\left(I_{y}\right) \approx V\left(c_{y}\right) p_{y}^{2}+c_{y}^{2} V\left(p_{y}\right) . \tag{4}
\end{equation*}
$$

A covariance term is not included in the variance estimator since there is no correlation between the estimator of the proportion positive and the mean CPUE given presence. The two estimators are derived independently and have been shown to not covary for a given year (Christman, unpublished).

The submodels of the delta-lognormal model were built using a backward selection procedure based on type 3 analyses with an inclusion level of significance of $\alpha=0.05$. Binomial submodel performance was evaluated using AIC, while the performance of the lognormal submodel was evaluated based on analyses of residual scatter and QQ plots in addition to AIC. Variables that could be included in the submodels were:

## Submodel Variables (GOM)

Year: 1995-1997, 1999-2015
Depth: $9-183 \mathrm{~m}$ (continuous)
Area: Atlantic, Eastern GOM, Central GOM, Western GOM
Hook Type: Circle hook, J-hook

## Results and Discussion

## Size and Distribution

The distribution of Sandbar Shark is presented in Figure 1, with annual abundance and distribution presented in Appendix Figure 1. There were 5 to 163 Sandbar Sharks captured per year (Table 2). Of the 1,184 Sandbar Shark captured, a total of 683 were measured from 1995 2015 with an average fork length of 1490 mm . In addition, there were also 481 individuals that only had an estimated length taken, mainly prior to 2005 when a sling was developed to allow for measurements of large sharks (Figure 2). Even with the addition of the estimated lengths, the average fork length only increases to 1497 mm .

## Abundance Index

For the NMFS BLL abundance index of Sandbar Shark, year, area and depth were retained in the binomial submodel, while only year was retained in the lognormal submodels. A summary of the factors used in the analysis is presented in Appendix Table 1. Table 3 summarizes backward selection procedure used to select the final set of variables used in the submodels and their significance. The AIC for the binomial and lognormal submodels were $18,907.4$ and $1,116.3$, respectively. The diagnostic plots for the binomial and lognormal submodels are shown in Figures 3, and indicated the distribution of the residuals is approximately normal. Annual abundance indices are presented in Table 4 and Figure 4.

## Appendix

Appendix Table 1. Summary of the factors used in constructing the Sandbar Shark abundance index from the NMFS bottom longline survey data.

| Factor | Level | Number of Observations | Number of Positive Observations | Proportion Positive | Mean CPUE |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Year | 1995 | 117 | 20 | 0.17094 | 0.22762 |
| Year | 1996 | 109 | 9 | 0.08257 | 0.10666 |
| Year | 1997 | 228 | 23 | 0.10088 | 0.25123 |
| Year | 1999 | 161 | 10 | 0.06211 | 0.06646 |
| Year | 2000 | 195 | 19 | 0.09744 | 0.13670 |
| Year | 2001 | 249 | 30 | 0.12048 | 0.20910 |
| Year | 2002 | 376 | 42 | 0.11170 | 0.16221 |
| Year | 2003 | 255 | 30 | 0.11765 | 0.17440 |
| Year | 2004 | 251 | 27 | 0.10757 | 0.13368 |
| Year | 2005 | 74 | 5 | 0.06757 | 0.05898 |
| Year | 2006 | 186 | 12 | 0.06452 | 0.08559 |
| Year | 2007 | 134 | 14 | 0.10448 | 0.19568 |
| Year | 2008 | 125 | 17 | 0.13600 | 0.17699 |
| Year | 2009 | 195 | 46 | 0.23590 | 0.42849 |
| Year | 2010 | 157 | 42 | 0.26752 | 0.59702 |
| Year | 2011 | 293 | 63 | 0.21502 | 0.43920 |
| Year | 2012 | 162 | 56 | 0.34568 | 0.71169 |
| Year | 2013 | 181 | 42 | 0.23204 | 0.53905 |
| Year | 2014 | 137 | 35 | 0.25547 | 0.55002 |
| Year | 2015 | 183 | 63 | 0.34426 | 0.88890 |
| Area | Atlantic | 806 | 152 | 0.18859 | 0.36327 |
| Area | Eastern GOM | 1458 | 282 | 0.19342 | 0.37171 |
| Area | Central GOM | 758 | 76 | 0.10026 | 0.21426 |
| Area | Western GOM | 746 | 95 | 0.12735 | 0.20345 |
| Hook Type | Circle hook | 3051 | 533 | 0.17470 | 0.33685 |
| Hook Type | J hook | 717 | 72 | 0.10042 | 0.16900 |

Appendix Figure 1. Annual survey effort and catch of Sandbar Shark from the NMFS bottom longline survey (1995-2015).
