Sustainable Fisheries Division Contribution Number: SFD-2018-008
Keywords: CPUE, catch, effort, recreational fisheries, red grouper

## 1. Introduction

The recreational fishery in the Gulf of Mexico is surveyed by the Marine Recreational Fishery Statistics Survey conducted by NOAA Fisheries, the Texas Marine Sport-Harvest Monitoring Program conducted by the Texas Parks and Wildlife Department, and the Headboat Survey (HBS) conducted by NOAA Fisheries. The HBS has monitored catch and effort from party (head) boats in the Gulf of Mexico since 1986. HBS data were used to construct an index of red grouper catch rates in the Gulf of Mexico following the same procedures as SEDAR42. The index was constructed using Generalized Linear Mixed Models, and a delta-lognormal approach.

## 2. Materials and Methods

## Headboat Survey

The Headboat Survey collects data on the catch and effort for individual headboat trips. Reported information includes landing date and location, vessel identification, the number of anglers, fishing location, trip duration and/or type (half/three-quarter/full/multi-day, day/night, morning/afternoon), and catch by species in number and weight.

HBS data were used to characterize abundance trends of red grouper in the Gulf of Mexico. Catch per unit effort (CPUE) was calculated on an individual trip basis. CPUE for each trip was defined as the number of red grouper landed divided by the effort, where effort was the product of the number of anglers and the total hours fished. To estimate effort for each trip type, the following assumptions were necessary:
$1 / 2$ day trip $=5$ hours fished
$3 / 4$ day trip $=7$ hours fished
Full day trip $=10$ hours fished

## Data Filtering Techniques

The following data preparation and filtering techniques from SEDAR 42 were applied to the 1986-2017 HBS dataset:

1. Observations in the Gulf of Mexico were limited to two regions (SW FL, NW FL \& AL).
2. Only half-day am, half-day pm, three-quarter day, and full-day trips were retained.
3. Trips with possible errors in effort information or catch amount were excluded.
4. Trips during the closed season for red grouper were excluded.
5. Trips were not separated into periods associated with different size limits.
6. The Stephens MacCall (2004) approach was used to restrict the dataset to those trips that likely encountered red grouper based on the trip's species composition.
7. Trips that reached bag limits for red grouper and aggregate groupers were retained.

## Standardization

A delta-lognormal approach (Lo et al., 1992) was used to develop standardized catch rate indices. This method combines separate generalized linear modeling (GLM) analyses of the proportion of trips that observed red grouper and the catch rates on positive trips to construct a single standardized index of abundance. A forward stepwise approach based on AIC was used during the construction of each GLM. In addition to screening using AIC, factors were also screened and not added to the model if the reduction in deviance per degree of freedom was less than one percent. The following factors were examined as possible influences on the proportion of positive trips, and the catch rates on positive trips:

| Factor | Levels | Details |
| :---: | :---: | :---: |
| Year | 32 | 1986-2017 |
| Area | 2 | NW FL \& AL, SW FL |
| Season | 4 | Dec-Feb, Mar-May, Jun-Aug, Sep- |
| Anglers* | 5 | Nov |
| Trip Type* | 3 | Full day, Half day, Three quarter day |
| *Trip type and number of anglers were only explored as factors |  |  |
| for modeling success. |  |  |

The factors above were examined for the binomial model based on success, where success was defined as whether or not a trip landed red grouper. However, the binomial component of the delta lognormal did not model success. Instead, the binomial component modeled the proportion of positive trips in each unique combination of variables associated with the fixed factors.

Once a set of fixed factors was identified, first level interactions were examined. The significance of these interactions was evaluated between nested models using the likelihood ratio test. Interactions were screened and were only retained if the model improvement was significant according to the likelihood ratio test ( $\mathrm{p}<0.0001$ ). Significant YEAR*FACTOR interaction terms were modeled as random effects. The final delta-lognormal model was fit using the SAS macro GLIMMIX and the SAS procedure PROC MIXED (SAS Institute Inc. 1997) following the procedures by Lo et al. (1992).

The variation in catch rates by vessel was examined using a "repeated measures" approach (Littell et al., 1998). The term 'repeated measures' refers to multiple measurements taken over time on the same experimental unit (i.e. vessel). Specifying the repeated measure "VESSEL" and the subject "VESSEL(YEAR)" allows PROC MIXED to model the covariance structure of the data. This is particularly important because catch rates may vary by vessel and because catch rates by a given vessel that are close in time can be more highly correlated than those far apart in time (Littell et al., 1998)

## 3. Results and Discussion

## Stephens and MacCall

The minimum difference between the predicted and the observed number of trips that reported red grouper occurred at the probability threshold of 0.37 (Figure 1a). Trips with a predicted probability that was greater than the critical threshold probability were identified as trips that targeted red grouper (Figure 2b). This method retained $28.3 \%$ of trips, and $51.5 \%$ of trips that reported red grouper. Prior to trip selection, there were 165,449 trips and the proportion positive was 0.277 , and after selection there were 46,782 trips and the proportion positive was 0.506 . Given these diagnostics, sufficient trips were retained to develop a standardized index of abundance.

## Annual Abundance Indices

Table 1 summarizes the standardized index and corresponding coefficients of variation, upper confidence limits, lower confidence limits, and nominal CPUE. Final deviance tables are included in Table 2. Tables 3-5, in appendix A, provide the number of observations, the number of positive observations, and the proportion of positive observations by year and factor.

The final models for the binomial and lognormal components were:
Proportion Positive $=$ YEAR + TRIP TYPE + AREA + YEAR*AREA + YEAR*TRIP TYPE $\ln (\mathrm{CPUE})=$ YEAR + AREA + SEASON + YEAR*AREA + YEAR*SEASON

The standardized index, with $95 \%$ confidence intervals, is shown in Figure 2. Diagnostics for each component of the GLM are provided in Figures 3 and 4. The over-dispersion parameter for the binomial component was 6.55 . Figure 5 provides a comparison of the headboat index that resulted from the current analysis to the headboat index derived during SEDAR42. Note that for SEDAR 61 the YEAR*TRIP TYPE interaction in contrast to SEDAR 42 where this interaction was not significant in the likelihood ratio test when modeling the proportion positive.

## Comments on Adequacy for Assessment

The headboat index presented in this working paper reflects the continuity index of the Headboat index that was deemed adequate for use in the SEDAR 42 assessment. This decision was based on the long time series and large spatial coverage associated with the Headboat Survey. This index is associated with high variability and future recommendations should address how to most appropriately model interactions and how to most appropriately calculate the variance associated with the index.

## 6. Figures

Figure 1: (a) Plot of the difference between the number of records in which red grouper are observed and the number in which they are predicted to occur for each probability threshold. (b) Histogram of probabilities generated for each trip by the species-based regression. The dashed vertical line indicates the critical value where false prediction is minimized.

Figure 2: Standardized indices with $95 \%$ confidence intervals and nominal CPUE for the Gulf of Mexico red grouper headboat index.

Figure 3. Diagnostic plots for the binomial model. Shown here are the predicted (solid line) and observed proportion of positive trips by year (a), and the residuals from the binomial model by year (b), area (c), and trip type (d).

Figure 4. Diagnostic plots for the lognormal model of catch rates on positive trips. Shown here are the frequency distribution of catch rates (a), the cumulative normalized residuals (b), and the distribution of residuals by year (c), area (d), and season (e). The red lines represent the expected normal distribution.

Figure 5: Standardized headboat index for SEDAR 61 compared to the headboat indices provided in for SEDAR 42. For comparison, both indices have been normalized by their respective means.
