General recreational and commercial age and length composition weighting for Southeast U.S. Spanish mackerel (Scomberomorus maculatus)

Sustainable Fisheries Branch, National Marine Fisheries Service, Southeast Fisheries Science Center, 101 Pivers Island Rd., Beaufort, NC 28516

October 2021

## Introduction

The fishery-dependent data collection for lengths and ages may be biased due to sampling protocols, state-specific sampling effort, or other non-random methods. The selection of fish from which to collect ageing structures may be biased because the selection process is rarely randomized. One technique to overcome bias in the length sampling is to weight samples by the associated landings at a spatial and temporal scale at which the bias is expected. Usually this is unknown and samples are weighted at the finest scale available without losing data (e.g. length samples with no associated landings). In this document we describe how the length data were weighted and how these weightings are extended to the age data. These methods have been used in previous SEDAR assessments and completed between the data and assessment workshops.

## Data Description

## Commercial-general

Biological sample data were obtained from the NMFS/SEFSC Trip Interview Program (TIP). Data were filtered to eliminate those records: 1) that included a size or effort bias, 2) where lengths were collected using a non-random method, 3 ) were not from commercial trips, 4) were selected by quota sampling, or 5) the data was not collected shore-side. These data were further limited to those that could be assigned a year, gear, and state. Length samples were assigned a state based on landing location or sample location if there was no landing location assigned.

## Lengths

## Commercial

The number of commercial length samples by gear are in Table 1.
All Spanish mackerel lengths were converted to FL in mm using the formula provided by the SEDAR 28 Life History Group and binned into one-centimeter intervals. The length data and landings data were initially grouped into five categories; 1) handlines, 2) cast nets, 3) gillnets, 4) pound nets, and other (defined as longline, sink net, seine net, trammel net and trawl net).

Due to limited spatial samples for the age compositions the gillnet gear was the only fleet that had sufficient samples to develop weighted compositions.

## Recreational

## Headboat Survey Biological Sampling

Lengths were collected from 1972 to 2020 by headboat dockside samplers. From 1972 to 1975, only North Carolina and South Carolina were sampled whereas Georgia and northeast Florida were sampled beginning in 1976. The Southeast Region Headboat Survey conducted dockside sampling for the entire range of Atlantic waters along the southeast portion of the US from the NC-VA border through the Florida Keys beginning in 1978.

## MRIP Biological Sampling

The MRIP angler intercept survey includes the sampling of fish lengths from the harvested (landed, whole condition) catch. Up to 15 of each species landed per angler interviewed are measured to the nearest millimeter ( mm ) along a center line (defined as tip of snout to center of tail along a straight line, not curved over body). Weights are typically collected for the same fish measured. When time is constrained a weight may be collected without a length measurement.

Lengths were excluded in the SEDAR 28 assessment and due to limited spatial sampling for the age samples, the recreational lengths were not needed to weight the age compositions.

## Ages

## Commercial

The number of commercial Spanish mackerel otoliths sampled by gear and region are in Table 2.
Due to age limited spatial samples for the age compositions the gillnet gear was the only fleet that had sufficient samples to weight the length compositions. All other fleets (including the general recreational fleet) were provided as a nominal composition.

## Recreational

Aging structures and other biological samples are not collected during MRIP assignments because of concerns over the introduction of bias to survey data collection. Biological samples (scales, otoliths, spines, stomachs and gonads) are collected by the SRHS and processed for aging, diet studies, and maturity studies. Aging structures provided from the charter boat and private boat modes were collected ad hoc by MRIP state subcontractors and SRHS port agents.

The number of recreational Spanish mackerel otoliths sampled by region are in Table 3.

## Weighting methods

The finest scale to weight the SEFSC-TIP length data was by year and state for each of the gear groupings (gillnet). For each year, the state-specific length composition was multiplied by the proportion of landings from that state. The weighted state-specific length compositions were then combined and scaled to sum to one.

The fishery-dependent age composition estimates were weighted to correct biases in age composition due to non-representative sampling. This weighting method was adapted from a technique to reduce bias associated with non-representative age sampling to produce unbiased growth curves (Chih, 2009) and has been previously used in SEDAR assessments. Lengths are recorded for each fish sampled for age. A reweighting value ( $R W$ ) associated with the year $(j)$ and length interval $(i)$ of the age sample was assigned to each age sample by fishery as in the formula:

$$
R W_{i j}=\frac{L C_{i j}}{O L_{i j} / T O_{j}}
$$

where $L C_{i j}$ is the weighted length composition value associated with the year $j$ and length interval $i$ of each aged fish, $O L_{i j}$ is the number of aged samples in length interval $i$ and year $j$, and $T O_{j}$ is the total number of aged samples in year $j$. This weighting corrects for a potential sampling bias of age samples relative to length samples (Chih, 2009). The numerator in this method differs slightly from the method used by Chih in that the length composition is weighted by the landings. The minimum sample size cutoff for length and age compositions was 30 fish per area and 10 trips per area.

## Results

## Lengths

The weighted length composition for the gillnet fishery was very similar to the nominal composition for most years (Figure 1).

## Ages

## Commercial

The weighted age compositions are very similar to the nominal age compositions for the gillnet fishery (Figure 2). The nominal age compositions for the remaining fleets are in Figures 3-5.

## General Recreational

Due to limited spatial samples the nominal age composition for the recreational fleet are in Figure 6.

## Discussion

There is minimal influence when weighting the length or age composition for Spanish mackerel. However, the weighted compositions are recommended for use as a matter of protocol and to remove whatever minimal bias may be present.
